Successes of Reinforcement Learning

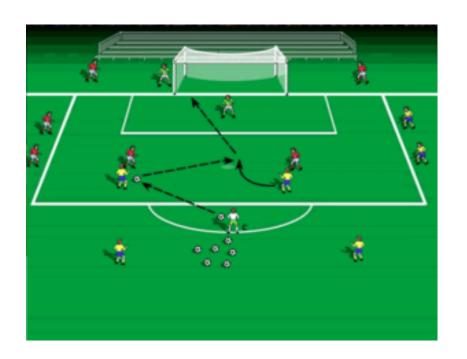

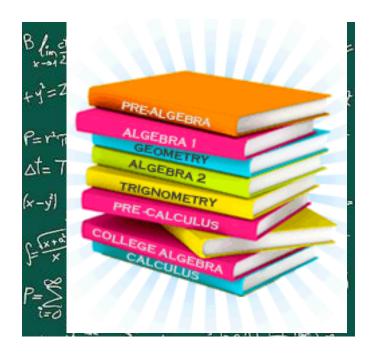

Approaching or passing human level performance

BUT

Can take *millions* of episodes! People learn this <u>MUCH</u> faster

People Learn via Curricula

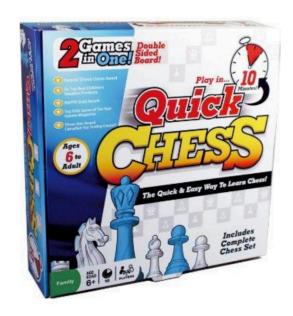

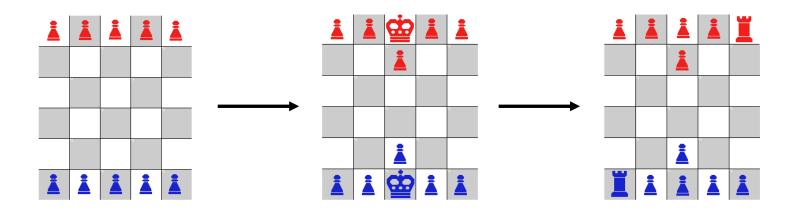

People are able to learn a lot of complex tasks very efficiently

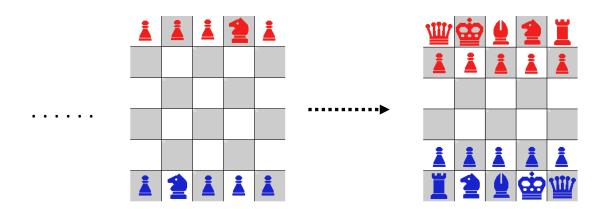

Example: Quick Chess

- Quickly learn the fundamentals of chess
- 5 x 6 board
- Fewer pieces per type
- No castling
- No en-passant

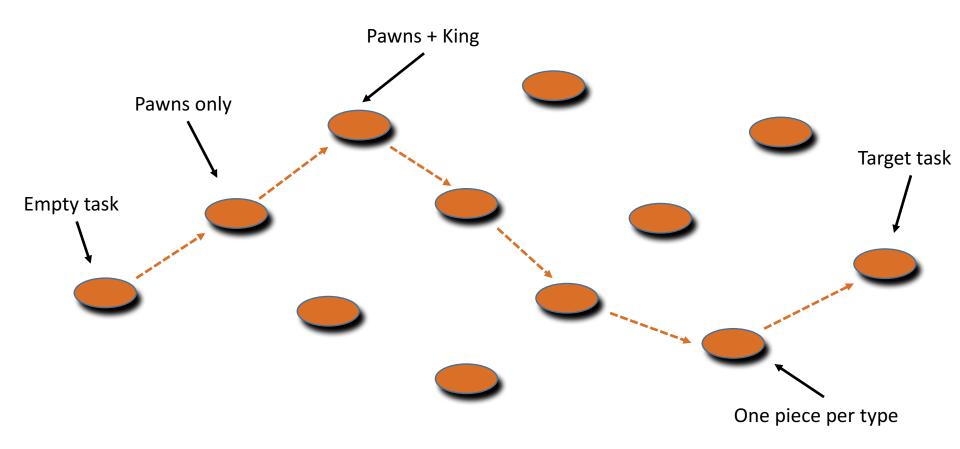

Example: Quick Chess

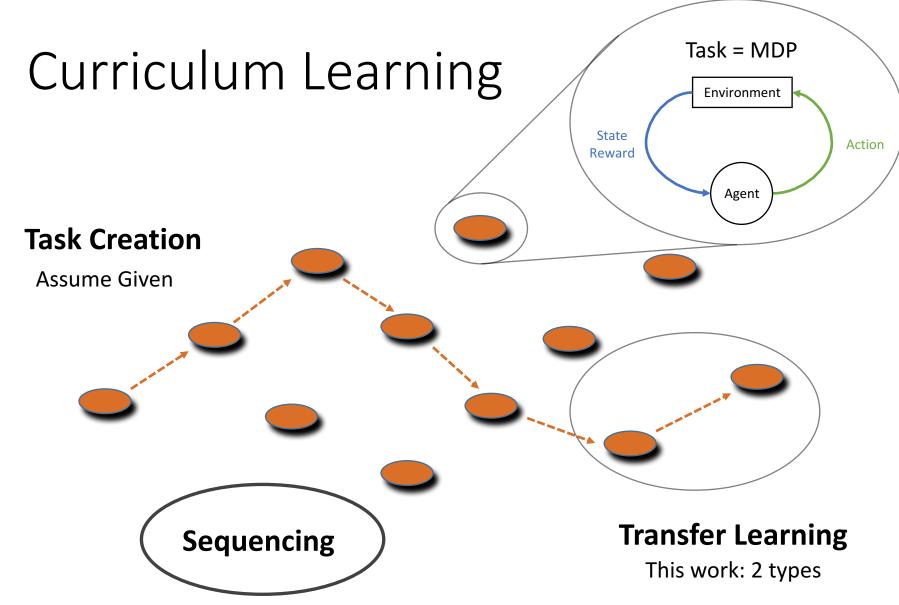

Task Space

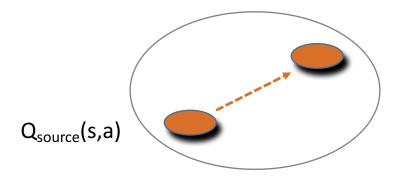

- Quick Chess is a curriculum designed for people
- We want to do something similar automatically for autonomous agents

 Curriculum learning is a complex problem that ties task creation, sequencing, and transfer learning

Value Function Transfer

 Initialize Q function in target task using values learned in a source task

- Assumptions:
 - Tasks have overlapping state and action spaces
 - OR an inter-task mapping is provided
 - Existing related work on learning mappings

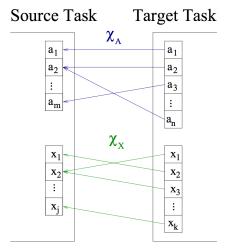

Image credit: Taylor and Stone, JMLR 2009

Reward Shaping Transfer

Reward function in target task augmented with a shaping reward
 f:

$$r'(s, a, s') = r(s, a, s') + f(s, a, s')$$
New Reward Old Reward Shaping Reward

 Potential-based advice restricts f to be difference of potential functions:

$$f(s, a, s') = \Phi(s', \pi(s')) - \Phi(s, a)$$

Use the value function of the source as the potential function:

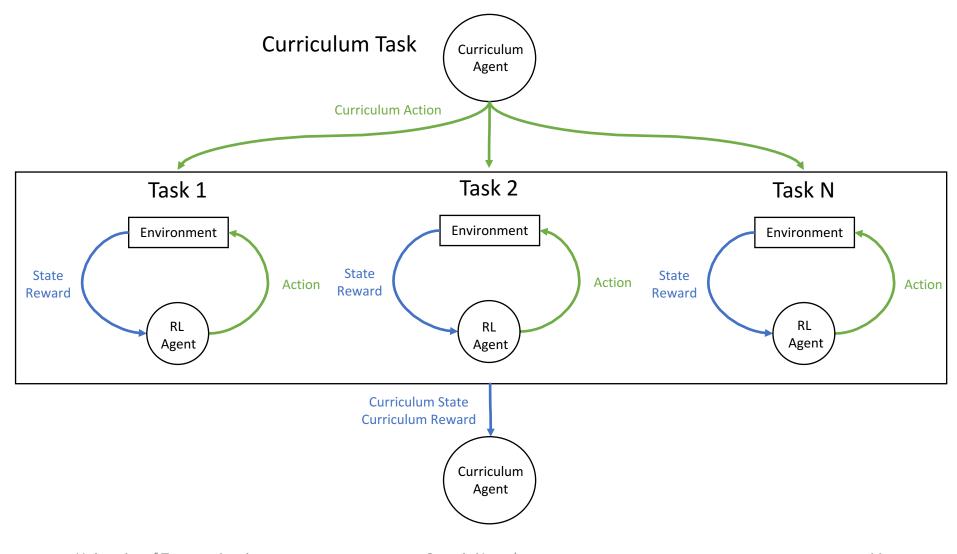

$$\Phi(s, a) = Q_{source}(s, a)$$

The Problem: Autonomous Sequencing

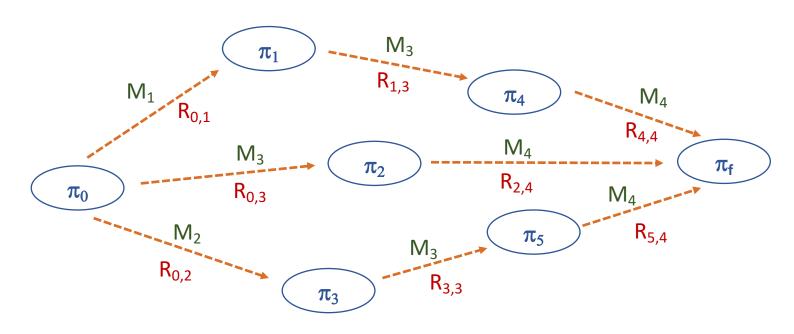

- Existing work heuristic-based, such as examining performance on the target task, and using heuristics to select next task
- In this work, we use learning to do sequencing

Sequencing as an MDP

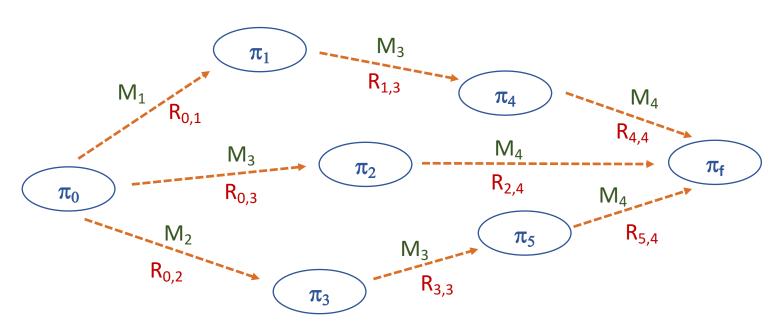

University of Texas at Austin Sanmit Narvekar 11

Sequencing as an MDP

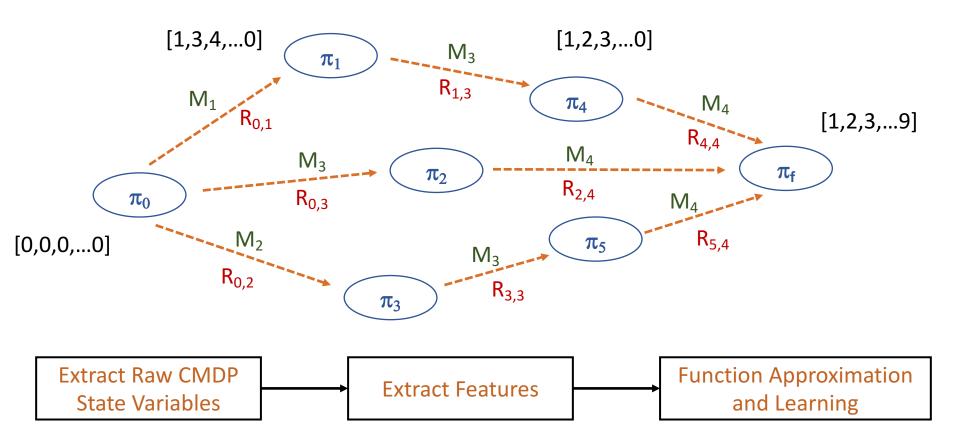

- State space S^c : All policies π_i an agent can represent
- Action space A^c : Different tasks M_i an agent can train on
- Transition function $p^c(s^c,a^c)$: Learning task a^c transforms an agent's policy s^c
- Reward function $r^c(s^c, a^c)$: Cost in time steps to learn task a^c given policy s^c

Sequencing as an MDP

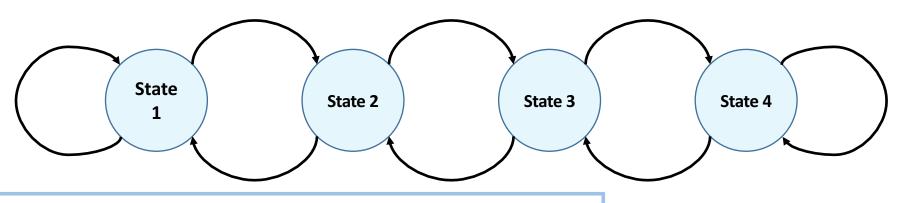

- A policy π^c : $S^c \to A^c$ on this curriculum MDP (CMDP) specifies which task to train on given learning agent policy π_i
- Essentially training a teacher
- How to do learning over CMDP?
- How does CMDP change when transfer method changes?

Learning in Curriculum MDPs

- Express raw CMDP state using the weights of base agent's VF/policy
- Extract features so that similar policies (CMDP states) are "close" in feature space

Example: Discrete Representations

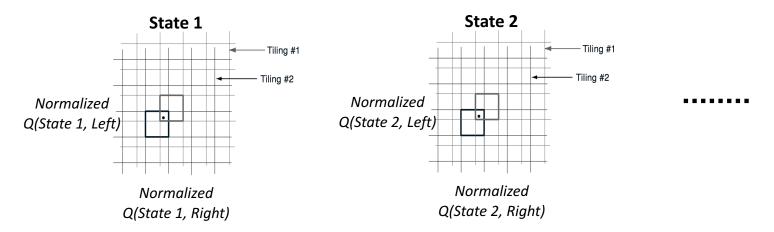

| CMDP State 1 | | | | | |
|--------------|------|-------|---------------|--|--|
| | Left | Right | Policy | | |
| State 1 | 0.3 | 0.7 | \rightarrow | | |
| State 2 | 0.1 | 0.9 | \rightarrow | | |
| State 3 | 0.4 | 0.6 | \rightarrow | | |
| State 4 | 0.0 | 1.0 | \rightarrow | | |

| CMDP State 2 | | | | | |
|--------------|------|-------|---------------|--|--|
| | Left | Right | Policy | | |
| State 1 | 0.2 | 0.8 | \rightarrow | | |
| State 2 | 0.2 | 0.8 | \rightarrow | | |
| State 3 | 0.2 | 0.8 | \rightarrow | | |
| State 4 | 0.3 | 0.7 | \rightarrow | | |

| CMDP State 3 | | | | | |
|--------------|------|-------|---------------|--|--|
| | Left | Right | Policy | | |
| State 1 | 0.7 | 0.3 | ← | | |
| State 2 | 0.9 | 0.1 | ← | | |
| State 3 | 0.6 | 0.4 | ← | | |
| State 4 | 0.0 | 1.0 | \rightarrow | | |

 CMDP states 1 and 2 encode very similar policies, and should be close in CMDP representation space

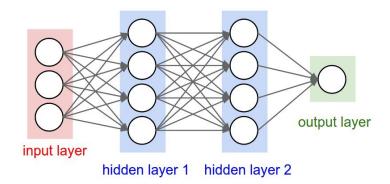

Example: Discrete Representations

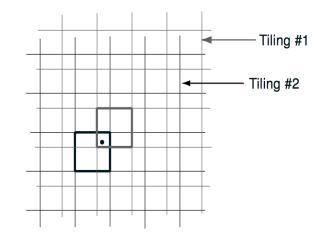

- One approach: use tile coding
- Create a separate tiling on a state-by-state level
- When comparing CMDP states, the more similar the policies are in a primitive state, the more common tiles will be activated
- Each primitive state contributes equally towards the similarity of the CMDP state

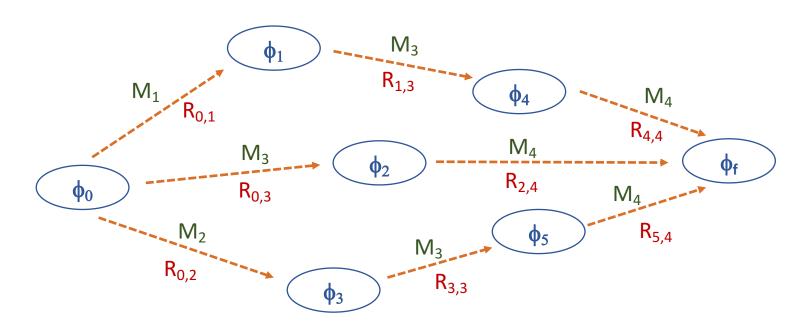

Continuous CMDP Representations

- In continuous domains, weights are not local to a state
- Needs to be done separately for each domain
 - Neural networks
 - Tile coding
 - Etc...
- If the base agent uses a linear function approximator, one can use tile coding over the parameters as before

Changes in Transfer Algorithm

- Transfer method directly affects CMDP state representation and transition function
- CMDP states represent "states of knowledge," where knowledge represented as VF, shaping reward, etc.
- Similar process can be done if knowledge parameterizable

Experimental Results

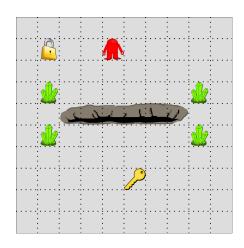

Evaluate whether curriculum policies can be learned

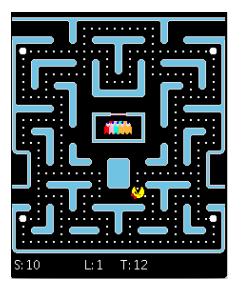

Grid world

- Multiple base agents
- Multiple CMDP state representations

Pacman

- Multiple transfer learning algorithms
- How long to train on sources?

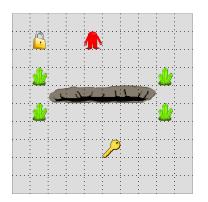

Grid world Setup

Agent Types

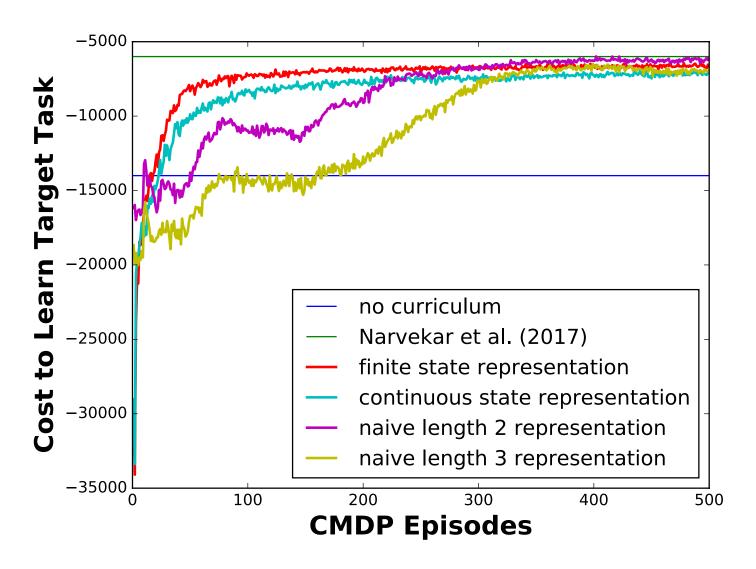

- Basic Agent
 - State: Sensors on 4 sides that measure distance to keys, locks, etc.
 - Actions: Move in 4 directions, pickup key, unlock lock
- Action-dependent Agent
 - State difference: weights on features are shared over 4 directions
- Rope Agent
 - Action difference: Like basic, but can use rope action to negate a pit

CMDP Representations

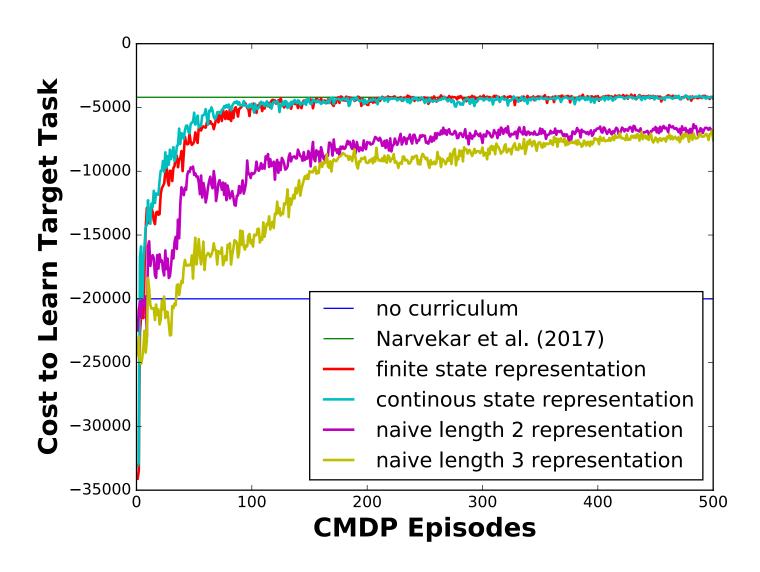

- Finite State Representation
 - For discrete domains, groups and normalizes raw weights state-by-state to form CMDP features
- Continuous State Representation
 - Directly uses raw weights of learning agent as features for CMDP agent

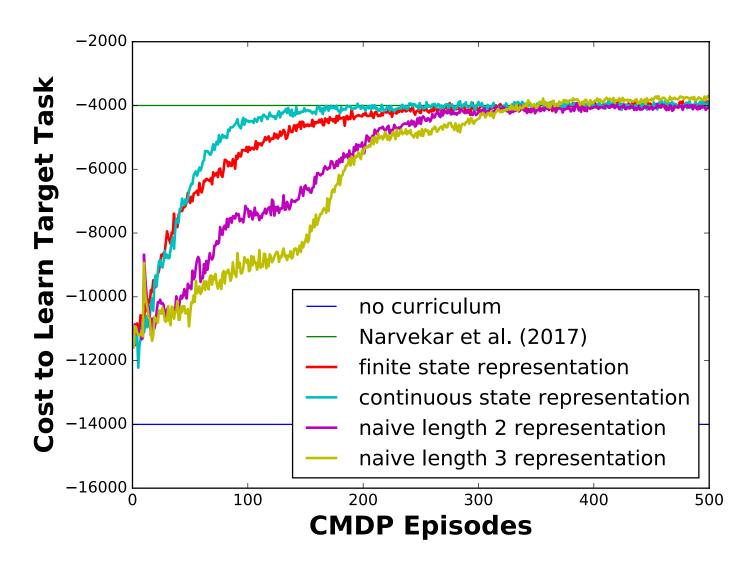

Basic Agent Results

Action-Dependent Agent Results

Rope Agent Results

Pacman Setup

Agent Representation

Action-dependent egocentric features

CMDP Representation

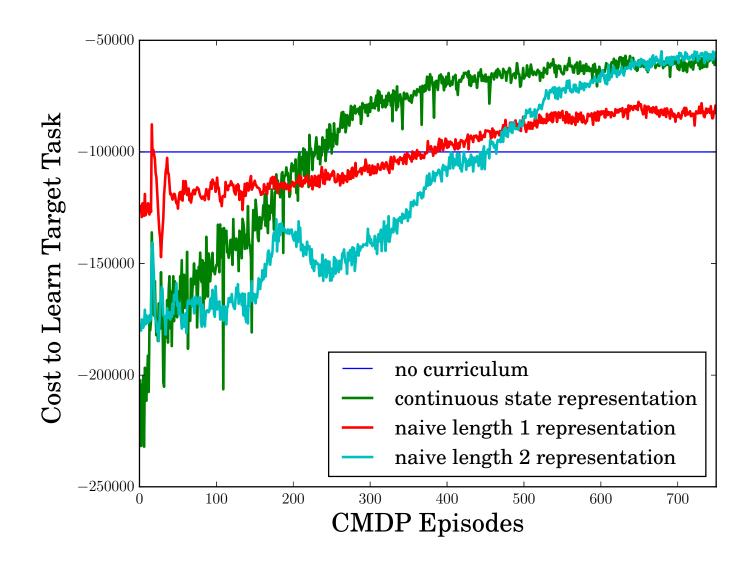

- Continuous State Representation
 - Directly uses raw weights of learning agent as features for CMDP agent

Transfer Methods

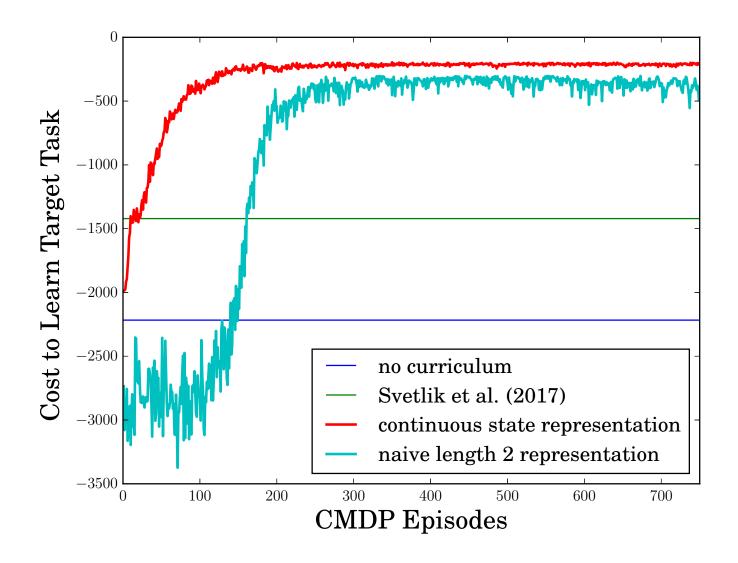

- Value Function Transfer
- Reward Shaping Transfer

How long to train on a source task?

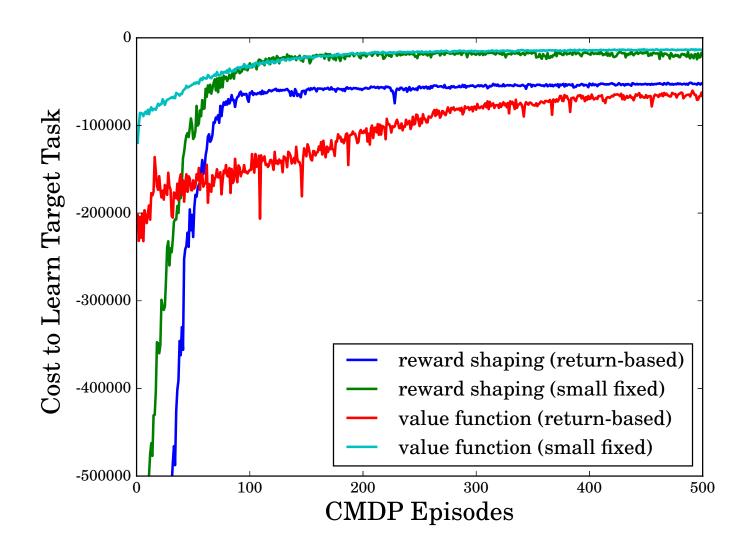

Pacman Value Function Transfer

Pacman Reward Shaping Transfer

How long to train?

Summary

- Generalize/Formulate curriculum generation as an MDP
- Demonstrate curriculum policies can be learned, and is robust to:
 - Learning agent state/action representation
 - CMDP representations
 - Transfer algorithm used
