For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

## Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- If the `backup` role does not exist, create it with the `REPLICATION` privilege when [Configuring the Database Cluster](#):

```
CREATE ROLE backup WITH LOGIN REPLICATION;
```

- If the `backup` role already exists, grant it with the `REPLICATION` privilege:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the `pg_hba.conf` file, allow replication on behalf of the `backup` role.
- Make sure the parameter `max_wal_senders` is set high enough to leave at least one session available for the backup process.
- Set the parameter `wal_level` to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the [STREAM](#) WAL mode.

### Note

If you are planning to rely on `.pgpass` for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

## Setting up Continuous WAL Archiving

Making backups in the PAGE backup mode, performing [PITR](#) and making backups with the [ARCHIVE](#) WAL delivery mode require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the `wal_level` parameter is higher than `minimal`.
- If you are configuring archiving on the primary, `archive_mode` must be set to `on` or `always`. To perform archiving on a standby, set this parameter to `always`.
- Set the `archive_command` parameter, as follows:

```
archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --  
instance=instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and `remote_options` only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the [ARCHIVE](#) WAL mode, backups in the PAGE backup mode, as well as perform [PITR](#).

You can view the current state of the WAL archive using the `show` command. For details, see [the section called "Viewing WAL Archive Information"](#).

If you are planning to make PAGE backups and/or backups with [ARCHIVE](#) WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the [archive\\_timeout](#) Postgres Pro parameter **on the primary**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to a standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

### Note

Instead of using the [archive-push](#) command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/instance_name` directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

### Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the [pg\\_receivewal](#) utility. In this case, `pg_receivewal -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivewal`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivewal`.

## Setting up Backups from a Standby

`pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the [hot\\_standby](#) parameter to `on`.
- On the primary server, set the [full\\_page\\_writes](#) parameter to `on`.
- To perform standalone backups on a standby, complete all the steps in section [Setting up STREAM Backups](#).
- To perform archive backups on a standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backups from a standby server have the following limitations:

- If a standby is promoted to a primary during the backup process, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the primary, and not to use tools like `pg_compresslog` as [archive\\_command](#) to remove full-page writes from WAL files.

## Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the [amcheck](#) or [amcheck\\_next](#) extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
```

```
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

## Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the backup role only in the database **used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

## Configuring the Remote Mode

`pg_probackup` supports the remote mode that allows you to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

### Set up SSH

If you are going to use `pg_probackup` in remote mode via SSH, complete the following steps:

1. Install `pg_probackup` on both systems: `backup_host` and `postgres_host`.
2. For communication between the hosts set up a passwordless SSH connection between the `backup_user` user on `backup_host` and the `postgres` user on `postgres_host`:

```
backup_user@backup_host:~$ ssh-copy-id postgres@postgres_host
```

Where:

- `backup_host` is the system with *backup catalog*.
  - `postgres_host` is the system with the Postgres Pro cluster.
  - `backup_user` is the OS user on `backup_host` used to run `pg_probackup`.
  - `postgres` is the user on `postgres_host` under which Postgres Pro cluster processes are running. For Postgres Pro 11 or higher a more secure approach can be used thanks to [group access](#) feature.
3. If you are going to rely on [continuous WAL archiving](#), set up a passwordless SSH connection between the `postgres` user on `postgres_host` and the `backup` user on `backup_host`:
- ```
postgres@postgres_host:~$ ssh-copy-id backup_user@backup_host
```
4. Make sure `pg_probackup` on `postgres_host` can be located when a connection via SSH is made. For example, for Bash, you can modify `PATH` in `~/.bashrc` of the `postgres` user (above the line in `bashrc` that exits the script for non-interactive shells). Alternatively, for `pg_probackup` commands, specify the path to the directory containing the `pg_probackup` binary on `postgres_host` via the [--remote-path](#) option.

`pg_probackup` in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [delete](#), [catchup](#), [archive-push](#), and [archive-get](#).
- Operating in remote mode requires `pg_probackup` binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main `pg_probackup` process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.
- The main `pg_probackup` process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.

- The main process is usually started on *backup\_host* and connects to *postgres\_host*, but in case of `archive-push` and `archive-get` commands the main process is started on *postgres\_host* and connects to *backup\_host*.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main `pg_probackup` process, which exits with an error.
- Compression is always done on *postgres\_host*, while decompression is always done on *backup\_host*.

### Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

### Note

Setting the number of threads (`-j/--threads` option) to a value greater than 10 for `pg_probackup` working in the remote mode via SSH may result in the actual number of SSH connections exceeding the maximum allowed number of simultaneous SSH connections on the remote server and consequently lead to an “ERROR: Agent error: kex\_exchange\_identification: Connection closed by remote host” error. To correct the error, either reduce the number of `pg_probackup` threads or adjust the value of `MaxStartups` configuration parameter of the remote SSH server. If SSH is set up as a `xinetd` service on the remote server, adjust the value of the `xinetd per_source` configuration parameter rather than `MaxStartups`.

## Configuring S3 Connectivity

`pg_probackup` supports S3 interface for storing backups. Backup data is transferred to and from S3 without saving it in intermediate locations thus eliminating the need of having a large temporary storage.

An example configuration with a remote agent and a cloud storage (S3) is shown in [Figure I.1](#).

**Figure I.1. `pg_probackup` setup with a remote agent and S3**

In this figure, the following logical components are shown:

**Backup server**

A server where the main process of `pg_probackup` runs and where local backups are stored.

**Database server**

A server with a database instance that needs to be backed up or restored.

**Remote agent**

A secondary `pg_probackup` process running on the database server. Only applicable to the remote mode.

**Cloud storage**

A cloud storage for backups.

**Set up Access to S3 Storage**

If you are going to use `pg_probackup` with S3 interface, complete the following steps:

- Create a bucket with a unique and meaningful name in the S3 storage for you future backups.
- Create `ACCESS_KEY` and `SECRET_ACCESS_KEY` tokens to be used for secure connectivity instead of your username and password.
- For communication between `pg_probackup` and S3 server, set values of environment variables corresponding to your S3 server. For example:

```
export PG_PROBACKUP_S3_HOST=127.0.0.1
export PG_PROBACKUP_S3_PORT=9000
export PG_PROBACKUP_S3_REGION=ru-msk
export PG_PROBACKUP_S3_BUCKET_NAME=test1
export PG_PROBACKUP_S3_ACCESS_KEY=admin
export PG_PROBACKUP_S3_SECRET_ACCESS_KEY=password
export PG_PROBACKUP_S3_HTTPS=ON
```

Alternatively, you can provide S3 server settings in the S3 configuration file (see the `--s3-config-file` option in the section [S3 Options](#) for details).

It makes sense to specify S3 server settings if `--s3=minio`, as described in the section [S3 Options](#).

The following environment variables can be specified:

`PG_PROBACKUP_S3_HOST`

Address or list of addresses of the S3 server. A list of one or several semicolon-delimited addresses. Do not add a semicolon after the last address in the list. Each address can include the port number, separated by a colon. If the port number is not specified, the value of `PG_PROBACKUP_S3_PORT` is assumed. Do not add a colon if the port number is not specified.

For example:

```
export PG_PROBACKUP_S3_PORT=80
export PG_PROBACKUP_S3_HOST="127.0.0.1:9000;10.4.13.56:443;172.17.0.1"
```

In this example, for the “127.0.0.1” address, the port 9000 is explicitly specified, for “10.4.13.56”, the port 443 is specified, while for the “172.17.0.1” address, port 80, specified through `PG_PROBACKUP_S3_PORT`, will be used.

If any of the specified addresses gets unavailable while `pg_probackup` is in operation, requests to the S3 storage are distributed between the rest of the specified addresses. That is, when several addresses are specified, `pg_probackup` performs load balancing of S3 requests.

`PG_PROBACKUP_S3_PORT`

The port of the S3 server.

`PG_PROBACKUP_S3_REGION`

The region of the S3 server.

`PG_PROBACKUP_S3_BUCKET_NAME`

The name of the bucket on the S3 server.

PG\_PROBACKUP\_S3\_ACCESS\_KEY  
PG\_PROBACKUP\_S3\_SECRET\_ACCESS\_KEY

Secure tokens on the S3 server.

PG\_PROBACKUP\_S3\_HTTPS

The protocol to be used. Possible values:

- ON or HTTPS — use HTTPS
- Other than ON or HTTPS — use HTTP

PG\_PROBACKUP\_S3\_BUFFER\_SIZE

The size of the read/write buffer for communicating with S3, in MiB. The default is 16.

PG\_PROBACKUP\_S3\_RETRIES

The maximum number of attempts to execute an S3 request in case of failures. The default is 3.

PG\_PROBACKUP\_S3\_TIMEOUT

The maximum amount of time to execute an HTTP request to the S3 server, in seconds. The default is 300.

PG\_PROBACKUP\_S3\_IGNORE\_CERT\_VER

Don't verify the certificate host and peer. The default is ON.

PG\_PROBACKUP\_S3\_CA\_CERTIFICATE

Specify the path to file with trust Certificate Authority (CA) bundle.

PG\_PROBACKUP\_S3\_CA\_PATH

Specify the directory with trust CA certificates.

PG\_PROBACKUP\_S3\_CLIENT\_CERT

Setup SSL client certificate.

PG\_PROBACKUP\_S3\_CLIENT\_KEY

Setup private key file for TLS and SSL client certificate.

## Setting up PTRACK Backups

### Note

PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps.

### Note

The permissions required for the role that will perform PTRACK backups (the `backup` role in the examples below) are listed in [the section called “Configuring the Database Cluster”](#). The role must have permissions only in the database used for connection to the Postgres Pro server.

For Postgres Pro 11 or higher:

1. Create PTRACK extension:

```
CREATE EXTENSION ptrack;
```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

### Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

## Usage

### Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance=instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. Thus, to perform incremental backups, it is necessary to have the last parent full backup with the status `OK` or `DONE` in the directory. If the parent full backup has the `MERGING` or `MERGED` status, an incremental backup cannot be performed.

For example, if merge has already been launched with a single full backup, an attempt to perform an incremental backup will end with the following messages:

```
WARNING: Valid full backup on current timeline 1 is not found, trying to look up on
previous timelines
WARNING: Cannot find valid backup on previous timelines
ERROR: Create new full backup before an incremental one
```

### ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

### STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During [backup](#) `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using [continuous archiving](#), STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

#### Page Validation

If [data\\_checksums](#) are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 300 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

#### External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the [set-config](#) command with the `--external-dirs` option.

## Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance=instance_name]] [-D data_dir]
[connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck\\_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the `checkdb` command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

## Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

### Note

The backup validation includes checking checksums for CFS files.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running [backup](#) and [restore](#) commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the [validate](#) command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify *backup\_id* via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If *backup\_id* is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `SBOL6P` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance=instance_name -i SBOL6P --recovery-  
target-time="2024-04-10 18:18:26+03"
```

If you specify the *backup\_id* of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

## Restoring a Cluster

To restore the database cluster from a backup, run the [restore](#) command with at least the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -i backup_id
```

Where:

- *backup\_dir* is the backup catalog that stores all backup files and meta information.
- *instance\_name* is the backup instance for the cluster to be restored.
- *backup\_id* specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the [primary\\_conninfo](#) parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a `STREAM` backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For `ARCHIVE` backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -j 4 -  
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg\\_probackup in the Remote Mode”](#).

## Note

By default, the `restore` command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

### Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using [incremental restore options](#) with the `restore` command.

To restore the database cluster from a backup in incremental mode, run the `restore` command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name -D data_dir -
I incremental_mode
```

Where `incremental_mode` can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the `pg_control` in the data directory to obtain redo LSN and redo TLI, which allows you to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, [data checksums](#) parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the `pg_control` file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that `pg_control` contain valid information. Therefore it is not recommended to use LSN mode in any situation, where `pg_control` cannot be trusted or has been tampered with: after `pg_resetxlog` execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, `pg_probackup` will check, that postmaster in given destination directory is not running and `system-identifier` is the same as in the backup.

Suppose you want to return an old primary as a replica after switchover using incremental restore in LSN mode:

| Instance<br>Data | Version<br>WAL | ID<br>Zalg | Recovery Time<br>Zratio       | Recovery Time |            | Mode  | WAL Mode | TLI | Time |
|------------------|----------------|------------|-------------------------------|---------------|------------|-------|----------|-----|------|
|                  |                |            |                               | Start LSN     | Stop LSN   |       |          |     |      |
| node             | 17             | SBOL8S     | 2024-04-09 18:19:43.707720+03 | DELTA         | STREAM     | 16/15 |          |     |      |
| 3s 114MB         | 64MB           | lz4        | 1.42                          | 0/3C003020    | 0/3E8D4930 | OK    |          |     |      |

```

### Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

#### Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the [restore](#) commands.

To restore the specified databases only, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance=instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

**Note**

The `template0` and `template1` databases are always restored.

**Note**

Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the `hot standby` parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

**Performing Point-in-Time (PITR) Recovery**

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the `restore` command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-time="2024-04-10 18:18:26+03"
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target-name="before_app_upgrade"
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target="latest"
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance=instance_name --recovery-target='immediate'
```

**Using pg\_probackup in the Remote Mode**

`pg_probackup` supports the remote mode that allows you to perform `backup` and `restore` operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro

instance to be backed up is located on a remote system. You must have `pg_probackup` installed on both systems.

### Note

`pg_probackup` relies on passwordless SSH connection for communication between the hosts.

### Note

In addition to SSH connection, `pg_probackup` uses a regular connection to the database to manage the remote operation. See the section [Configuring the Database Cluster](#) for details of how to set up a database connection.

The typical workflow is as follows:

- On your backup host, configure `pg_probackup` as explained in the section [Installation and Setup](#). For the [add-instance](#) and [set-config](#) commands, make sure to specify [remote options](#) that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in [PAGE](#) mode, or rely on [ARCHIVE](#) WAL delivery mode, or use [PITR](#), configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the [archive-push](#) and [archive-get](#) commands, you must specify the [remote options](#) that point to the backup host with the backup catalog.
- Run [backup](#) or [restore](#) commands with [remote options on the backup host](#). `pg_probackup` connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port 2302, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port 2302, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

Restoring an [ARCHIVE](#) backup or performing [PITR](#) in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port 2302 and user `backup` on backup catalog host with address `192.168.0.3` via port 2303, run:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance=instance_name --remote-user=postgres
--remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/
pg_probackup" archive-get -B "backup_dir" --instance=instance_name --wal-file-path=%p
--wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

### Note

The remote mode is currently unavailable for Windows systems.

## Running pg\_probackup on Parallel Threads

[backup](#), [restore](#), [merge](#), [delete](#), [catchup](#), [checkdb](#), and [validate](#) processes can be executed on several parallel threads. This can significantly speed up `pg_probackup` operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL -j 4
```

### Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

### Important

A technique is implemented that prevents repeatable copying of one file when `pg_probackup` runs on multiple threads. With this technique, however, when disks are slow or the system is overloaded, parallel copying might fail. To handle this situation, resolve issues with your system resources.

## Configuring pg\_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune `pg_probackup` configuration.

For example, [backup](#) and [checkdb](#) commands use a regular Postgres Pro connection. To avoid specifying [connection options](#) each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the [set-config](#) command.

### Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define [remote](#), [retention](#), [logging](#), and [compression](#) settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance=instance_name
```

You can override the settings defined in `pg_probackup.conf` when running `pg_probackup` [commands](#) via the corresponding environment variables and/or command line options.

### Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent `pg_probackup` commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default `pg_probackup` tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

### Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

### Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

| Instance | Version | ID   | Recovery Time | Mode                          | WAL Mode   | TLI     | Time   |
|----------|---------|------|---------------|-------------------------------|------------|---------|--------|
| Data     | WAL     | Zalg | Zratio        | Start LSN                     | Stop LSN   | Status  |        |
| node     | 17      |      | SBOL94        | 2024-04-09 18:19:56.603355+03 | FULL       | ARCHIVE | 1/0 6s |
| 377MB    | 16MB    | lz4  | 1.46          | 0/41000028                    | 0/420000C0 | OK      |        |
| node     | 17      |      | SBOL8S        | 2024-04-09 18:19:43.707720+03 | DELTA      | STREAM  | 1/1 3s |
| 114MB    | 64MB    | lz4  | 1.42          | 0/3C003020                    | 0/3E8D4930 | OK      |        |
| node     | 17      |      | SBOL8G        | 2024-04-09 18:19:32.594670+03 | PTRACK     | STREAM  | 1/1 4s |
| 30MB     | 16MB    | zlib | 2.23          | 0/31000028                    | 0/310029E0 | OK      |        |
| node     | 17      |      | SBOL83        | 2024-04-09 18:19:22.269595+03 | PAGE       | STREAM  | 1/1 7s |
| 46MB     | 32MB    | pglz | 1.44          | 0/29000028                    | 0/2A0000F8 | OK      |        |
| node     | 17      |      | SBOL7P        | 2024-04-09 18:19:06.557301+03 | FULL       | STREAM  | 1/0 6s |
| 144MB    | 16MB    | zstd | 2.47          | 0/22000028                    | 0/220001C8 | OK      |        |

For each backup, the following information is provided:

- Instance — the instance name.
- Version — Postgres Pro major version.
- ID — the backup identifier.
- Recovery time — the earliest moment for which you can restore the state of the database cluster.
- Mode — the method used to take this backup. Possible values: FULL, PAGE, DELTA, PTRACK.

- **WAL Mode** — WAL delivery mode. Possible values: `STREAM` and `ARCHIVE`.
- **TLI** — timeline identifiers of the current backup and its parent.
- **Time** — the time it took to perform the backup.
- **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For `STREAM` backups, the total size of the backup can be calculated as `Data + WAL`.
- **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- **compress-alg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- **Status** — backup status. Possible values:
  - **OK** — the backup is complete and valid.
  - **DONE** — the backup is complete, but was not validated.
  - **RUNNING** — the backup is in progress.
  - **MERGING** — the backup is being merged.
  - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
  - **DELETING** — the backup files are being deleted.
  - **CORRUPT** — some of the backup files are corrupt.
  - **ERROR** — the backup was aborted because of an unexpected error.
  - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.
  - **HIDDEN\_FOR\_TEST** — a test script marked the backup as nonexistent. (`pg_probackup` never sets this status by itself.)

You can restore the cluster from the backup only if the backup status is `OK` or `DONE`.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = lz4
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
xlog-block-size = 8192
checksum-version = 1
program-version = 2.7.3
server-version = 17

#Result backup info
timelineid = 1
start-lsn = 0/41000028
stop-lsn = 0/420000C0
```

```
start-time = '2024-04-09 18:19:52+03'
end-time = '2024-04-09 18:19:58+03'
end-validation-time = '2024-04-09 18:19:59+03'
recovery-xid = 757
recovery-time = '2024-04-09 18:19:56.603355+03'
data-bytes = 395651278
wal-bytes = 16777216
uncompressed-bytes = 578552566
pgdata-bytes = 578552248
status = OK
primary_conninfo = 'user=backup channel_binding=prefer host=localhost
port=5432 sslmode=prefer sslcompression=0 sslcertmode=allow sslsni=1
ssl_min_protocol_version=TLSv1.2 gssencmode=prefer krbsrvname=postgres gssdelegation=0
target_session_attrs=any load_balance_hosts=disable'
content-crc = 3862224379
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on a standby? Possible values: `1`, `0`.
- `block-size` — the [block\\_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data\\_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: `1`, `0`.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `end-validation-time` — the backup validation end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup meta-information.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance=instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
  {
    "instance": "node",
    "backups": [
      {
        "id": "SBOL94",

```

### Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance=instance_name] --archive
```

**pg\_probackup** displays the list of all the available WAL files grouped by timelines. For example:

```

ARCHIVE INSTANCE 'node'

```

| TLI      | Parent TLI | Switchpoint | Min Segno                        | Max Segno                        | N  |
|----------|------------|-------------|----------------------------------|----------------------------------|----|
| segments | Size       | Zratio      | N backups                        | Status                           |    |
| 1        | 0          | 0/0         | 0000000100000000000000000000001B | 00000001000000000000000000000042 | 40 |
|          | 640MB      | 1.00        | 5                                | OK                               |    |

For each timeline, the following information is provided:

- **TLI** — timeline identifier.
- **Parent TLI** — identifier of the timeline from which this timeline branched off.
- **Switchpoint** — LSN of the moment when the timeline branched off from its parent timeline.
- **Min Segno** — the first WAL segment belonging to the timeline.
- **Max Segno** — the last WAL segment belonging to the timeline.
- **N segments** — number of WAL segments belonging to the timeline.
- **Size** — the size that files take on disk.
- **Zalg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as  $N \text{ segments} * wal\_segment\_size * wal\_block\_size / \text{Size}$ .
- **N backups** — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- **Status** — status of the WAL archive for this timeline. Possible values:
  - **OK** — all WAL segments between **Min Segno** and **Max Segno** are present.
  - **DEGRADED** — some WAL segments between **Min Segno** and **Max Segno** are missing. To find out which files are lost, view this report in the JSON format. This status may appear if several WAL files (in the middle of the sequence) were deleted by the `delete` command with the `--delete-wal` option according to the retention policy. This status does not affect the restore correctness, but it can be impossible to perform PITR of the cluster to some recovery targets.

To get more detailed information about the WAL archive in the JSON format, run the command:

```

pg_probackup show -B backup_dir [--instance=instance_name] --archive --format=json

```

The sample output is as follows:

```
INFO: checking WAL file name "0000000010000000000000000001B"

```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

## Configuring Retention Policy

With `pg_probackup`, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

### Removing Redundant Backups

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance=instance_name --retention-redundancy=2
--retention-window=7
```

It is recommended to always keep at least two last parent full backups to avoid errors when creating incremental backups.

To clean up the backup catalog in accordance with retention policy, you have to run the [delete](#) command with [retention flags](#), as shown below, or use the [backup](#) command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running `backup` or `delete` commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 6 and `--retention-redundancy` option set to 2, and you have the following backups available on August 01, 2024:

```
BACKUP INSTANCE 'node'
```

| Instance                   | Version | ID     | Recovery Time          | Mode       | WAL Mode | TLI | Time | Data   |

| node                       | 17      | SGUYZ2 | 2024-07-19 09:49:53+03 | DELTA      | ARCHIVE  | 1/1 | 5s   | 6442kB |
| 16MB                       | zstd    | 1,07   | 0/5000028              | 0/60000C0  | OK       |     |      |        |
| node                       | 17      | SGT4B1 | 2024-07-18 09:49:52+03 | FULL       | ARCHIVE  | 1/0 | 5s   | 11MB   |
| 16MB                       | zstd    | 2,89   | 0/2000028              | 0/3003A28  | OK       |     |      |        |

If you run the `delete` command with the `--delete-expired` flag, the backups with IDs `SGT4B1`, `SGUYZ2`, and `SGWTN3` will be removed as they are expired both according to the retention window and due to redundancy (the required set of full backups has already been retained). `SGUYZ2` and `SGWTN3` will also be removed since the base full backup is expired.

Running the `delete` command with the `--merge-expired` flag will merge backups `SH48B3` and `SH62Z5` with `SH9SB5`. The merge will occur with `SH9SB5` as it is the first non-expired delta backup, which can be merged with expired delta backups `SH62Z5` and expired full backup `SH48B3`.

```
pg_probackup delete -B backup_dir --instance=node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

| Instance | Version | ID     | Recovery Time          | Mode       | WAL Mode | TLI | Time | Data |

The `Time` field for the merged backup displays the time required for the merge.

### Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --expire-time="2027-04-09 18:21:32+00"
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the `backup` command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance=instance_name -b FULL --expire-time="2027-04-09 18:21:32+00"
```

To check if the backup is pinned, run the `show` command:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2024-04-09 18:21:32+00'
expire-time = '2027-04-09 18:21:32+00'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id --ttl=0
```

### Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

### Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the `set-config` command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all

the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the [delete](#) or [backup](#) command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the [delete](#) and [backup](#) commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance=node
```

| Instance | Version | ID     | Recovery Time                 | Mode       | WAL Mode   | TLI    | Time |
|----------|---------|--------|-------------------------------|------------|------------|--------|------|
| Data     | WAL     | Zalg   | Zratio                        | Start LSN  | Stop LSN   | Status |      |

```

```
INFO: checking WAL file name "00000001000000000000000006F"
INFO: checking WAL file name "00000001000000000000000006F.00000028.backup"
```

```
ARCHIVE INSTANCE 'node'
```

| TLI segments | Parent TLI Size | Switchpoint Zratio | Min Segno N backups | Segno Status                    | Max Segno                 | N  |
|--------------|-----------------|--------------------|---------------------|---------------------------------|---------------------------|----|
| 1            | 0               | 0/0                | 6                   | 0000000100000000000000054<br>OK | 000000010000000000000006F | 28 |

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance=node --delete-wal --wal-depth=1
```

```
INFO: checking WAL file name "00000001000000000000000006F"
INFO: checking WAL file name "00000001000000000000000006F.00000028.backup"
```

```
ARCHIVE INSTANCE 'node'
```

| TLI segments | Parent TLI Size | Switchpoint Zratio | Min Segno N backups | Segno Status                    | Max Segno                 | N |
|--------------|-----------------|--------------------|---------------------|---------------------------------|---------------------------|---|
| 1            | 0               | 0/0                | 6                   | 000000010000000000000006F<br>OK | 000000010000000000000006F | 1 |

Alternatively, you can use the `--wal-depth` option with the `backup` command:

```
pg_probackup backup -B backup_dir --instance=node -b DELTA --wal-depth=1 --delete-wal
```

```
INFO: checking WAL file name "000000010000000000000000071"
INFO: checking WAL file name "000000010000000000000000071.00000028.backup"
```

```
ARCHIVE INSTANCE 'node'
```

| TLI segments | Parent TLI Size | Switchpoint Zratio | Min Segno N backups | Segno Status                    | Max Segno                 | N |
|--------------|-----------------|--------------------|---------------------|---------------------------------|---------------------------|---|
| 1            | 0               | 0/0                | 7                   | 0000000100000000000000071<br>OK | 0000000100000000000000071 | 1 |

## Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows you to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the [remote](#) mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance=instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

## Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance=instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance=instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance=instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

## Cloning and Synchronizing Postgres Pro Instance

`pg_probackup` can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the `catchup` command. It can be useful in the following cases:

- To add a new standby server.

Usually, `pg_basebackup` is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with the primary.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with the primary and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from the primary.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands [CREATE TABLESPACE/DROP TABLESPACE](#) cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source server as follows:

- [Configure the database cluster](#) for the instance to copy.
- To copy from a remote server, [configure the remote mode](#).
- To use the PTRACK catchup mode, [set up PTRACK backups](#).

Before cloning/synchronizing a Postgres Pro instance, ensure that the source server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the [catchup](#) command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where `catchup_mode` can take one of the following values:

- **FULL** — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- **DELTA** — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- **PTRACK** — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

### Warning

PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set [STREAM](#) WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the server via replication protocol.

You can use [connection options](#) to specify the connection to the source database cluster. If it is located on a different server, also specify [remote options](#).

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pg-data` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK  
--remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-  
path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --  
exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --  
remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

## Command-Line Reference

### Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

#### version

```
pg_probackup version [--format=json]
```

Prints `pg_probackup` version and edition, as well as Postgres Pro version and edition.

If `--format=json` is specified, the output is printed in the JSON format. This may be needed for native integration with JSON-based applications, such as PPEM. Example of a JSON output:

```
pg_probackup version --format=json  
{  
  "pg_probackup":  
  {  
    "version": "2.8.2",  
    "edition": "enterprise"  
  },  
  "database":  
  {  
    "type": "Postgres Pro Enterprise",  
    "version": "16.3.1"  
  },  
  "compressions": [zlib, pglz, lz4, zstd]  
}
```

#### help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

#### init

```
pg_probackup init -B backup_dir [--skip-if-exists] [s3_options] [--help]  
[logging_options]
```

Initializes the backup catalog in *backup\_dir* that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified *backup\_dir* already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message. You can ignore this error by specifying the `--skip-if-exists` option. Although the backup will not be initialized, the application will return 0 code.

For details, see the section [Initializing the Backup Catalog](#).

#### **add-instance**

```
pg_probackup add-instance -B backup_dir -D data_dir --instance=instance_name
[--skip-if-exists] [s3_options] [--help] [logging_options]
```

Initializes a new backup instance inside the backup catalog *backup\_dir* and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified *data\_dir* data directory. If the catalog was already initialized, you can ignore the error by specifying `--skip-if-exists`.

For details, see the section [Adding a New Backup Instance](#).

#### **del-instance**

```
pg_probackup del-instance -B backup_dir --instance=instance_name [s3_options] [--help]
[logging_options]
```

Deletes all backups and WAL files associated with the specified instance.

#### **set-config**

```
pg_probackup set-config -B backup_dir --instance=instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options] [s3_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

#### **set-backup**

```
pg_probackup set-backup -B backup_dir --instance=instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [s3_options] [--help] [logging_options]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

```
--note=backup_note
```

Sets the text note for backup copy. If *backup\_note* contains newline characters, then only the substring before the first newline character will be saved. The maximum size of a text note is 1 KB. The *'none'* value removes the current note.

For all available pinning settings, see the section [Pinning Options](#).

#### **show-config**

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
[s3_options]
```

```
[--no-scale-units] [logging_options]
```

Displays all the current `pg_probackup` configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory and those that were provided on a command line. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

You can also specify the `--no-scale-units` option to display time and memory configuration settings in their base (unscaled) units. Otherwise, the values are scaled to larger units for optimal display. For example, if `archive-timeout` is 300, then 5min is displayed, but if `archive-timeout` is 301, then 301s is displayed. Also, if the `--no-scale-units` option is specified, configuration settings are displayed without units and for the JSON format, numeric and boolean values are not enclosed in quotes. This facilitates parsing the output.

To edit `pg_probackup.conf`, use the [set-config](#) command.

#### show

```
pg_probackup show -B backup_dir
[--help] [--instance=instance_name [-i backup_id | --archive]] [--format=plain|json]
  [--no-color] [--show-symlinks] [s3_options]
[logging_options]
```

Shows the contents of the backup catalog. If `instance_name` and `backup_id` are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

If the `--show-symlinks` option is specified, the command also shows the links between [merged](#) backups and the original full backups that incremental backups were merged to.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

#### backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance=instance_name
[--help] [-j num_threads] [--progress]
[--backup-threads num_threads] [--validate-threads num_threads]
[-C] [--stream [-S slot_name] [--temp-slot[=true|false|on|off]]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password]
[--write-rate-limit=bitrate]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options] [s3_options]
```

Creates a backup copy of the Postgres Pro instance.

`-b mode`

`--backup-mode=mode`

Specifies the backup mode to use. Possible values are: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

`--backup-threads num_threads`

Specifies the number of threads for copying files. Overrides the `j/--threads` option for file copying.

`--validate-threads num_threads`

Specifies the number of threads for the backup validation. Overrides the `j/--threads` option for the backup validation.

`-C`  
`--smooth-checkpoint`  
Spreads out the checkpoint over a period of time. By default, `pg_probackup` tries to complete the checkpoint as soon as possible.

`--stream`  
Makes a **STREAM** backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot [=true|false|on|off]`  
Creates a *temporary* physical replication slot for streaming WAL from the backed up Postgres Pro instance. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-S slot_name`  
`--slot=slot_name`  
Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`  
Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E external_directory_path`  
`--external-dirs=external_directory_path`  
Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--write-rate-limit=bitrate`  
Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the backup:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total backup time.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

`--archive-timeout=wait_time`  
Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

`--skip-block-validation`  
Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

It is recommended to use this flag when creating a backup to an S3 storage. Due to some features of S3 storages, automatic validation may appear incorrect in this case. Skip automatic validation and then perform validation using a separate [validate](#) command.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the [validate](#) command once the backup is complete to detect possible issues.

`--note=backup_note`

Sets the text note for backup copy. If *backup\_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The *'none'* value removes current note.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), [Retention Options](#), [Pinning Options](#), [Remote Mode Options](#), [Compression Options](#), [Logging Options](#), and [S3 Options](#).

For details on usage, see the section [Creating a Backup](#).

## restore

```
pg_probackup restore -B backup_dir --instance=instance_name
[--help] [--dry-run] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options] [s3_options]
```

Restores the Postgres Pro instance from a backup copy located in the *backup\_dir* backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

`-R`

`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the [primary\\_conninfo](#) parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

`--primary-conninfo=primary_conninfo`

Sets the [primary\\_conninfo](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`  
`--primary-slot-name=slot_name`  
Sets the [primary\\_slot\\_name](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T OLDDIR=NEWDIR`  
`--tablespace-mapping=OLDDIR=NEWDIR`  
Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=OLDDIR=NEWDIR`  
Relocates an external directory included into the backup from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`  
Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`  
Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`  
Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--restore-command=cmdline`  
Sets the [restore\\_command](#) parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`  
Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, [incremental restore](#) with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`  
Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the [restore](#) command again.

`-X wal_dir`  
`--waldir=wal_dir`  
Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. `wal_dir` must be an absolute path, which must not already exist, but if it does, it must be empty.

For more details of the command settings, see sections [Common Options](#), [Recovery Target Options](#), [Remote Mode Options](#), [Remote WAL Archive Options](#), [Logging Options](#), [Partial Restore Options](#), and [S3 Options](#).

For details on usage, see the section [Restoring a Cluster](#).

### checkdb

```
pg_probackup checkdb
[-B backup_dir] [--instance=instance_name] [-D data_dir]
[--help] [-j num_threads] [--progress]
[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]
[connection_options] [logging_options]
[s3_options]
```

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

For the command to work correctly, when the backup instance is created in the S3 storage, you must specify [S3 options](#) on the command line or through environment variables.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the [amcheck](#) extension or the `amcheck_next` extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of `amcheck` installed.

`--checkunique`

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the `amcheck` extension is installed in the database.

The verification of unique constraints is only possible if in the version of the `amcheck` extension you are using, the `bt_index_check` function takes the `checkunique` parameter.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the `amcheck/amcheck_next` extension you are using, the `bt_index_check` function takes the `heapallindexed` parameter.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), [Logging Options](#), and [S3 Options](#).

For details on usage, see the section [Verifying a Cluster](#).

### validate

```
pg_probackup validate -B backup_dir
[--help] [--instance=instance_name] [-i backup_id]
[-j num_threads] [--progress] [--wal]
[--skip-block-validation]
[recovery_target_options] [logging_options] [s3_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If `instance_name` is not specified, `pg_probackup` validates all backups available in the backup catalog. If you specify the `instance_name` without any additional options, `pg_probackup` validates all the backups available for this backup instance. If you specify the `instance_name` with a [recovery target option](#) and/or a `backup_id`, `pg_probackup` checks whether it is possible to restore the cluster using these options. If the `--wal` option is specified, full check of the WAL archive will be performed instead of only checking WAL segments needed to restore the cluster.

For details, see the section [Validating a Backup](#).

### Note

The `TATLIN.OBJECT` S3 storage is an “eventually consistent” class system. In such systems, the reconciliation across nodes proceeds asynchronously. Therefore, if you are making a backup to the `TATLIN.OBJECT` S3 storage, perform backup validation not immediately after the backup, but some time later.

#### merge

```
pg_probackup merge -B backup_dir --instance=instance_name -i backup_id
[--dry-run] [--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For more details of the command settings, see sections [Common Options](#) and [Merging Backups](#).

#### delete

```
pg_probackup delete -B backup_dir --instance=instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options] [s3_options]
```

Deletes backup with specified *backup\_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections [Deleting Backups](#), [Retention Options](#), and [Configuring Retention Policy](#).

#### archive-push

```
pg_probackup archive-push -B backup_dir --instance=instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--dry-run] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
```

```
[--compress-level=compression_level]  
[remote_options] [logging_options] [s3_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance\_name* and *system-identifier*. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: Refuse to push WAL segment *segment\_name* into archive. Instance parameters mismatch.

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

The Postgres Pro server requests WAL segments one at a time. To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the [archive\\_command](#) Postgres Pro parameter to set up [continuous WAL archiving](#).

For more details of the command settings, see sections [Common Options](#), [Archiving Options](#), [Compression Options](#), and [S3 Options](#).

#### **archive-get**

```
pg_probackup archive-get -B backup_dir --instance=instance_name --wal-file-  
path=wal_file_path --wal-file-name=wal_file_name  
[-j num_threads] [--batch-size=batch_size]  
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]  
[--dry-run] [--help] [remote_options] [logging_options] [s3_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually if you use local storage for backups or remote mode.

If you use S3 interface, to ensure that the Postgres Pro server has access to S3 storage to fetch WAL files during restore, you can specify the `--s3-config-file` option that defines the S3 configuration file with appropriate configuration settings, as described in [the section called “S3 Options”](#).

The Postgres Pro server requests WAL segments one at a time. To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For more details of the command settings, see sections [Common Options](#), [Archiving Options](#), [Compression Options](#), and [S3 Options](#).

#### **catchup**

```
pg_probackup catchup -b catchup_mode  
--source-pgdata=path_to_pgdata_on_remote_server  
--destination-pgdata=path_to_local_dir  
[--help] [-j | --threads=num_threads] [--dry-run]  
[--write-rate-limit=bitrate]
```

```
[--stream [--temp-slot[=true|false|on|off]] [-P | --perm-slot] [-S | --slot=slot_name]]
[--exclude-path=PATHNAME]
[-T OLDDIR=NEWDIR]
[-X | --waldir=wal_dir]
[connection_options] [remote_options]
[logging_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

`-b catchup_mode`

`--backup-mode=catchup_mode`

Specifies the catchup mode to use. Possible values are: [FULL](#), [DELTA](#), and [PTRACK](#).

`--source-pgdata=path_to_pgdata_on_remote_server`

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

`--destination-pgdata=path_to_local_dir`

Specifies the path to the local data directory to copy to.

`-j num_threads`

`--threads=num_threads`

Sets the number of parallel threads for `catchup` process.

`--stream`

Copies the instance in [STREAM](#) WAL delivery mode, including all the necessary WAL files by streaming them from the server via replication protocol. For `catchup`, it is enabled by default.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the `catchup` operation:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total duration of the `catchup` operation.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

`-x=path_prefix`

`--exclude-path=path_prefix`

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

### Warning

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot [=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-P`

`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot/-S` option.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`-T OLDDIR=NEWDIR`

`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`-X wal_dir`

`--waldir=wal_dir`

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. `wal_dir` must be an absolute path, which must not already exist, but if it does, it must be empty to perform `catchup` with `--catchup-mode=FULL`.

For more details of the command settings, see sections [Common Options](#), [Connection Options](#), and [Remote Mode Options](#).

For details on usage, see the section [Cloning and Synchronizing Postgres Pro Instance](#).

## Options

This section describes command-line options for `pg_probackup` commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see [the section called “Configuring pg\\_probackup”](#).

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

## Common Options

The list of general options.

`--dry-run`

Initiates a trial run of the appropriate command, which does not actually do any changes, that is, it does not create, delete or move files on disk. This flag allows you to check that all the command options are correct and the command is ready to run. WAL streaming is skipped with `--dry-run`.

```
-B directory
--backup-path=directory
BACKUP_PATH
```

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the `pg_probackup` commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

```
-D directory
--pgdata=directory
PGDATA
```

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the `add-instance` command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

```
-i backup_id
--backup-id=backup_id
```

Specifies the unique identifier of the backup.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

```
--progress
```

Shows the progress of operations.

```
--help
```

Shows detailed information about the options that can be used with this command.

### Recovery Target Options

If `continuous WAL archiving` is configured, you can use one of these options together with `restore` or `validate` commands to specify the moment up to which the database cluster must be restored or validated.

```
--recovery-target=immediate|latest
```

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. Setting this value of `--recovery-target` also sets `--recovery-target-timeline` to `latest`.

```
--recovery-target-timeline=timeline
```

Specifies a particular timeline to be used for recovery:

- `current` — the timeline of the specified backup, default.
- `latest` — the timeline of the latest available backup.
- A numeric value.

```
--recovery-target-lsn=lsn
```

Specifies the LSN of the write-ahead log location up to which recovery will proceed.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

**Example:** `--recovery-target-time="2027-04-09 18:21:32+00"`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery\\_target\\_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery\\_target\\_action](#) the server should take when the recovery target is reached.

Default: `pause`

### Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: `0`

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

### Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttl`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2027-04-09 18:21:32+00"`

### Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of warning and error levels.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

### Note

All console log messages are going to `stderr`, so the output of [show](#) and [show-config](#) commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: none

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Note that the directory for log files is always created locally even if backups are created in the S3 storage. So be sure to pass a local path in `log_directory` when needed.

Default: `$BACKUP_PATH/log/`

`--log-format-console=log_format`

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the `set-config` command and that the `backup` command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.
- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=log_format`

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: `plain`

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: `kB`, `MB`, `GB`, `TB` (`kB` by default).

Default: `0`

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: `ms`, `s`, `min`, `h`, `d` (`min` by default).

Default: `0`

### Connection Options

You can use these options together with [backup](#), [catchup](#), and [checkdb](#) commands.

All [libpq environment variables](#) are supported.

```
-d dbname  
--pgdatabase=dbname  
PGDATABASE
```

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, PGDATABASE environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the PGUSER environment variable, or from the current user name if PGUSER variable is not set.

```
-h host  
--pghost=host  
PGHOST
```

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: localhost

```
-p port  
--pgport=port  
PGPORT
```

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: 5432

```
-U username  
--pguser=username  
PGUSER
```

User name to connect as.

```
-w  
--no-password
```

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a [pgpass](#) file or PGPASSWORD environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W  
--password
```

Forces a password prompt. (Deprecated)

### Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

```
--compress-algorithm=compression_algorithm
```

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `lz4`, `zstd`, `pglz`, and `none`. If set to any value, but `none`, this option enables compression that uses the corresponding algorithm. Both data files and WAL files are compressed. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

**Note**

pg\_probackup supports compression algorithms included in the Postgres Pro version. In particular:

- lz4 is supported for Postgres Pro Enterprise 13 and higher.
- zstd is supported for Postgres Pro Enterprise 11 and higher.

Default: none

`--compress-level=compression_level`

Defines the compression level. This option can be used together with the `--compress-algorithm` option. Possible values depend on the compression algorithm specified:

- 0 — 9 for `zlib`
- 1 for `pglz`
- 0 — 12 for `lz4`
- 0 — 22 for `zstd`

The value of 0 sets the default compression level for the specified algorithm:

- 6 for `zlib`
- 1 for `pglz`
- 9 for `lz4`
- 3 for `zstd`

**Note**

The pure lz4 algorithm has only one compression level — 1. So, if the specified compression algorithm is `lz4` and `--compress-level` is greater than 1, the `lz4hc` algorithm is actually used, which is much slower although does better compression.

Default: 1

`--compress`

Specifies the default compression algorithm and `--compress-level=1`. The default algorithm is selected among those supported by Postgres Pro according to the priorities: `zstd` (highest) -> `lz4` -> `zlib` -> `pglz`. The `--compress` option overrides the `--compression-algorithm` and `--compress-level` settings and cannot be specified together with them.

**Archiving Options**

These options can be used with the [archive-push](#) command in the [archive\\_command](#) setting and the [archive-get](#) command in the [restore\\_command](#) setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in `archive_command` and `restore_command`. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in `archive_command` and `restore_command`. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Used to speed up archiving in case of `archive-push` or to speed up recovery in case of `archive-get`. Sets the maximum number of WAL files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with [archive-push](#) command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if `archive_command` contains multiple commands. This option can be used only with [archive-push](#) command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with [archive-push](#) command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with [archive-get](#) command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with [archive-get](#) command.

### Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with [add-instance](#), [set-config](#), [backup](#), [catchup](#), [restore](#), [archive-push](#), and [archive-get](#) commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg\\_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.

- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see [ssh\\_config manual page](#).

### Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in `archive-get` used in the `restore_command` command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

### Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the `restore` command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

### Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the [restore](#) command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

### S3 Options

This section describes the options needed to store backups in private clouds. These options can be used with any commands that `pg_probackup` runs using S3 interface.

`--s3=s3_interface_provider`

Specifies the S3 interface provider. Possible values are:

- `minio` — MinIO object storage, compatible with S3 cloud storage service. With this provider, custom S3 server settings can be specified. The HTTP protocol, port 9000, and region `us-east-1` are used by default.
- `vk` — VK Cloud storage. With this provider, the S3 host address `hb.vkcs.cloud`, port 443, and HTTPS protocol are only used. Custom values of the host, port, and protocol are ignored. The default value of region is `ru-msk`.
- `aws` — Amazon S3 storage, offered by Amazon Web Services (AWS). With this provider, the S3 host address `bucket_name.s3.region.amazonaws.com`, port 443, and HTTPS protocol are only used. Custom values of the host, port, and protocol are ignored. The default value of region is `us-east-1`.

With `--s3=minio`, `pg_probackup` will work fine for a VK Cloud storage if the S3 host address, port and protocol are properly specified (host address is `hb.vkcs.cloud` or the one specified in the appropriate section of the VK Cloud profile, port 443, and HTTPS protocol). Do not specify `--s3=minio` for the Amazon S3 storage.

Once a `pg_probackup` command runs with the `--s3` option, `pg_probackup` starts running all commands that support parallel execution on 10 parallel threads (for details, see [the section called “Running pg\\_probackup on Parallel Threads”](#)). You can change the number of threads using the `-j/--threads` option.

`--s3-config-file=path_to_config_file`

Specifies the S3 configuration file. Settings in the configuration file override the environment variables. If this option is not specified, `pg_probackup` first looks for the S3 configuration file at `/etc/pg_probackup/s3.config` and then at `~postgres/.pg_probackup/s3.config`. The following is an example of the S3 configuration file:

```
access-key = ...
secret-key = ...
s3-host = localhost
s3-port = 9000
s3-bucket = s3demo
s3-region=us-east-1
s3-buffer-size = 32
s3-secure = on | https | http | off
```

## Testing and Debugging Options

This section describes options useful only in a test or development environment.

`--cfs-nondatfile-mode`

Instructs `backup` command to backup CFS in a legacy mode. This allows fine-tuning compatibility with `pg_probackup` versions earlier than 2.6.0. This option is mainly designed for testing.

`PGPROBACKUP_TESTS_SKIP_HIDDEN`

Instructs `pg_probackup` to ignore backups marked as hidden. Note that `pg_probackup` can never mark a backup as hidden. It can only be done by directly editing the `backup.control` file. This option can only be set with environment variables.

`--destroy-all-other-dbs`

By default, `pg_probackup` exits with an error if an attempt is made to perform a partial incremental restore since this destroys databases not included in the restore set. This flag allows you to suppress the error and proceed with the partial incremental restore (e.g., to keep a development database snapshot up-to-date with a production one). This option can be used with the `restore` command.

### Important

Never use this flag in a production cluster.

`PGPROBACKUP_TESTS_SKIP_EMPTY_COMMIT`

Instructs `pg_probackup` to skip empty commits after `pg_backup_stop`.

## Versioning

`pg_probackup` follows *semantic* versioning.

## Authors

Postgres Professional, Moscow, Russia.

## Credits

`pg_probackup` utility is based on `pg_arman`, which was originally written by NTT and then developed and maintained by Michael Paquier.

## vacuumlo

vacuumlo — remove orphaned large objects from a Postgres Pro database

### Synopsis

```
vacuumlo [option...] dbname...
```

### Description

vacuumlo is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the [lo](#) module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

### Options

vacuumlo accepts the following command-line arguments:

```
-l limit  
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max\\_locks\\_per\\_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

```
-n  
--dry-run
```

Don't remove anything, just show what would be done.

```
-v  
--verbose
```

Write a lot of progress messages.

```
-V  
--version
```

Print the vacuumlo version and exit.

```
-?  
--help
```

Show help about vacuumlo command line arguments, and exit.

vacuumlo also accepts the following command-line arguments for connection parameters:

```
-h host  
--host=host
```

Database server's host.

```
-p port  
--port=port
```

Database server's port.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

## Environment

```
PGHOST
PGPORT
PGUSER
```

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 37.15](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

## Author

Peter Mount <[peter@retep.org.uk](mailto:peter@retep.org.uk)>

## I.2. Third-Party Client Applications

This section covers third-party client applications included in the Postgres Pro Enterprise distribution. They can be run from anywhere, independent of where the database server resides. Note also that the `odbc` driver is available (see [Table 17.3](#) for details).

## pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

### Synopsis

```
pgbadger [connection-option...] [option...] [logfile...]
```

### Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

*logfile* can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass “-” as *logfile*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the [log\\_line\\_prefix](#) configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

[pgbouncer](#) log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at <https://pgbadger.darold.net/#reports>.

### Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

### Setup and Configuring

pgbadger is provided with Postgres Pro Enterprise as a separate pre-built package `pgbadger` (for the detailed installation instructions, see [Chapter 17](#)). Once you have pgbadger installed, complete the setup described in sections below.

#### [Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

#### [Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

```
sudo yum install perl-JSON-XS
```

### [Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- `zcat` for `gz`
- `bzcat` for `bz2`
- `lz4cat` for `lz4`
- `zstdcat` for `zst`
- `unzip` or `xz` for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"  
--zcat="C:\tools\unzip -p"
```

### Note

With the default autodetection of the compressed file format, you can mix `gz`, `bz2`, `lz4`, `xz`, `zip` and `zstd` log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

## Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

To enable SQL query logging and have the query statistics include actual query strings, set

```
log_min_duration_statement = 0
```

On a busy server you may want to increase this value to only log queries with a longer duration.

If you just want to report the duration and number of queries and do not want details of queries, set `log_min_duration_statement` to `-1`, which disables logging statement durations, and enable `log_duration`.

Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set `log_statement` to `all`, the setting of `log_min_duration_statement` will have no effect.

### Warning

Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in `log_line_prefix`.

It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for `stderr` logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable [log\\_statement](#) as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

## Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-16/data/log/postgres.log.2.gz /var/lib/pgpro/ent-16/data/
log/postgres.log.1.gz /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-16/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/ent-16/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/ent-16/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/ent-16/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@d %p %r %a : ' /var/lib/pgpro/ent-16/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/ent-16/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/ent-16/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/ent-16/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

## Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/ent-16/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/ent-16/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote [pgbouncer](#) log file together:

```
pgbadger /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

## Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in `pgbadger` follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks `pgbadger` may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

| Option | 1 CPU   | 2 CPU | 4 CPU | 8 CPU |
|--------|---------|-------|-------|-------|
| -j     | 1h41m18 | 50m25 | 25m39 | 15m58 |
| -J     | 1h41m18 | 54m28 | 41m16 | 34m45 |

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

| Option | 1 CPU   | 2 CPU | 4 CPU | 8 CPU |
|--------|---------|-------|-------|-------|
| -j     | 1h41m18 | 50m25 | 25m39 | 15m58 |
| -J     | 1h41m18 | 54m28 | 41m16 | 34m45 |

```
-j      | 20m15 | 9m56 | 5m20 | 4m20  
-J      | 20m15 | 9m49 | 5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

### Important

During parallel parsing, `pgbadger` generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

## Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/ent-16/data/log/ -mtime -7 -name  
"postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +%F`.html -l /var/reports/  
pgbadger_incremental_file.dat
```

But better turn on `pgbadger`'s automatic building incremental reports by specifying the `-I/--incremental` option. In this mode, `pgbadger` builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O/--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run `pgbadger` as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/ent-16/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode `pgbadger` will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run `pgbadger` in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-x/--extra-files` command-line option to force `pgbadger` to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O/--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/ent-16/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

If `pg_dump` is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by `pg_dump` on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

## Rebuilding Reports

To update all HTML reports after fixing a `pgbadger` report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js  
rm /path/to/reports/*.css  
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E/--explode` option if the reports were built with this option.

## Building Monthly Reports

By default, in the incremental mode `pgbadger` only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E/--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

## Choosing the Report File Format

The `pgbadger` report file format is determined by the extension of the file passed to the `-o/--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a `pgbadger` report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
ent-16/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/ent-16/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of `pgbadger` output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
ent-16/data/log/postgresql-2022-01-14_000000.log
```

## Return Codes

`pgbadger` return codes depend on how it terminated as follows:

- 0: was a success
- 1: died on error
- 2: has been interrupted using `Ctrl+C`, for example
- 3: the PID file already exists or cannot be created

- 4: no log file was specified on the command line

## Options

This section describes pgbadger command-line options.

`-a minutes`

`--average minutes`

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A minutes`

`--histo-average minutes`

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b datetime`

`--begin datetime`

Timestamp or time that specifies the start date/time for the data to be parsed in logs.

`-c host`

`--dbclient host`

Only report on log entries for the specified client host.

`-C`

`--nocomment`

Remove `/* ... */` comments from queries.

`-d name`

`--dbname name`

Only report on log entries for the specified database.

`-D`

`--dns-resolv`

Replace client IP addresses with their DNS names.

### Warning

This can considerably slow down pgbadger.

`-e datetime`

`--end datetime`

Timestamp or time that specifies the end date/time for the data to be parsed in logs.

`-E`

`--explode`

Build one report per each database. Global information not related to any database gets added to the postgres database report.

`-f logtype`

`--format logtype`

Specifies the log type.

**Possible values:** `syslog`, `syslog2`, `stderr`, `jsonlog`, `csv`, `pgbouncer`, `logplex`, `rds` and `redshift`. Use when `pgbadger` cannot detect the log format.

- `-G`  
`--nograph`  
Disables graphs in HTML output.
- `-h`  
`--help`  
Show detailed information about `pbadger` options and exit.
- `-H path`  
`--html-outdir path`  
Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by `-O/--outdir`.
- `-i name`  
`--ident name`  
Specifies the program name used to identify Postgres Pro messages in syslog logs.  
Default: `postgres`.
- `-I`  
`--incremental`  
Use the incremental mode, where reports will be generated by days in a separate directory specified by the `-O/--outdir` option.
- `-j number`  
`--jobs number`  
Specifies the number of jobs to run at the same time. When working with `csvlog` logs, `pgbadger` always runs as single job.  
Default: 1.
- `-J number`  
`--Jobs number`  
Specifies the number of log files to parse in parallel.  
Default: 1.
- `-l filename`  
`--last-parsed filename`  
Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.
- `-L filename`  
`--logfile-list filename`  
Specifies the file containing the list of log files to parse.
- `-m size`  
`--maxlength size`  
Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

`-M`  
`--no-multiline`

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

`-N name`  
`--appname name`

Only report on log entries for the specified application.

`-o filename`  
`--outfile filename`

Specifies the filename for the output and determines the report file format: `out.html`, `out.txt`, `out.bin` or `out.json`. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of `"-"` as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,  
for the respective output format.

`-O path`  
`--outdir path`

Specifies the directory where out files must be saved.

`-p string`  
`--prefix string`

Specifies the value of your custom `log_line_prefix` string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from the standard `log_line_prefix` strings, for example, if your prefix includes additional variables, such as client IP or application name. The string must contain escape sequences for time (`%t`, `%m` or `%n`) and processes (`%p` or `%c`).

`-P`  
`--no-prettify`

Disables SQL query code prettifier.

`-q`  
`--quiet`

Disables printing anything to stdout, even the progress bar.

`-Q`  
`--query-numbering`

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

`-r address`  
`--remote-host address`

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

`-R number`  
`--retention number`

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s number`  
`--sample number`

Specifies the number of query samples to store.

Default: 3.

`-S`  
`--select-only`

Only report on SELECT queries.

`-t number`  
`--top number`

Specifies the number of queries to store/display.

Default: 20.

`-T string`  
`--title string`

Specifies the title of the HTML report page.

`-u username`  
`--dbuser username`

Only report on log entries for the specified username.

`-U username`  
`--exclude-user username`

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`  
`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`  
`--version`

Show pgbadger version and exit.

`-w`  
`--watch-mode`

Only report errors, just like [Logwatch](#) can do.

`-W`  
`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages "Wide character in print".

`-x format`  
`--extension format`

Specifies the output format. Possible values: text, html, bin or json.

Default: html.

`-X`  
`--extra-files`  
In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

`-z command`  
`--zcat command`  
Specifies the full command to run the zcat program. Use if zcat, bzip2 or unzip is outside of your PATH directories.

`-Z +/-XX`  
`--timezone +/-XX`  
Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--pie-limit number`  
Specifies the number such that instead of lower pie data the sum will be shown.

`--exclude-query regexp`  
Specifies the regular expression such that matching queries will be excluded from the report. For example: “^(VACUUM|COMMIT)”. Can be used multiple times.

`--exclude-file filename`  
Specifies the path to the file that contains each regular expression to use to exclude matching queries from the report, one expression per line.

`--include-query regexp`  
Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: “(tbl1|tbl2)”.

`--include-file filename`  
Specifies the path to the file that contains each regular expression to use to include matching queries in the report, one expression per line.

`--disable-error`  
Turns off generation of an error report.

`--disable-hourly`  
Turns off generation of an hourly report.

`--disable-type`  
Turns off generation of a report on queries by type, database and user.

`--disable-query`  
Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

`--disable-session`  
Turns off generation of a session report.

`--disable-connection`  
Turns off generation of a connection report.

`--disable-lock`  
Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset name`

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator char`

Specifies the CSV field separator.

Default: “,”.

`--exclude-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .\*”. Can be used multiple times.

`--include-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .\*”. Can be used multiple times.

`--exclude-db name`

Specifies the name of the database to exclude related log entries from the report. For example: “outdated\_db”. Can be used multiple times.

`--exclude-appname name`

Specifies the name of the application to exclude related log entries from the report. For example: “pg\_dump”. Can be used multiple time.

`--exclude-line regexp`

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client name`

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl command`

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-ent-16`.

`--pid-dir path`

Specifies the path to store the PID file.

Default: `/tmp`.

`--pid-file filename`

Specifies the name of the PID file to manage concurrent execution of pgbadger.

Default: `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show [pgbouncer](#)-related menus in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday (by default, they start on Sunday) with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone +/-XX`

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated. The value can be an integer (e.g., 2), or a float, (e.g., 2.5).

`--prettify-json`

Prettify JSON output.

`--month-report YYYY-MM`

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report YYYY-MM-DD`

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by [auto\\_explain](#).

`--command cmd`

Specifies the command to run to retrieve log entries on stdin. pgbadger will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url URL`

Specifies the URL to override the URL of the graphical explain tool.

Default: <http://explain.depesz.com/>

`--tmpdir path`

Specifies the directory for temporary files.

Default: `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

`--dump-raw-csv`

Parse the log and dump the information into CSV format. No further processing is done, no report.

`--include-pid PID`

Only report events related to the session PID (%p). Can be used multiple times.

`--include-session ID`

Only report events related to the session ID (%c). Can be used multiple times.

`--histogram-query VAL`

Use custom inbound for query time histogram. Default inbound in milliseconds: 0,1,5,10,25,50,100,500,1000,10000.

`--histogram-session VAL`

Use custom inbound for session time histogram. Default inbound in milliseconds: 0,500,1000,30000,60000,600000,1800000,3600000,28800000.

## Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r/--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program ssh`

Specifies the path to the SSH program to use.

Default: `ssh`.

`--ssh-port port`

Specifies the SSH port for the connection.

Default: 22.

`--ssh-user username`

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity filename`

Specifies the path to the identity file.

`--ssh-timeout seconds`

Specifies the timeout in seconds in case of the SSH connection failure.

Default: 10.

`--ssh-option options`

Specifies the list of options to define SSH connection parameters. The following options are always used:

`-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey`

`-o PreferredAuthentications=hostbased,publickey`

## pg\_repack

pg\_repack — utility and Postgres Pro Enterprise extension to reorganize tables

### Synopsis

```
pg_repack [option...] [dbname]
```

### Description

*pg\_repack* is a Postgres Pro Enterprise extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike `CLUSTER` and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. *pg\_repack* is efficient to boot, with performance comparable to using `CLUSTER` directly.

*pg\_repack* is a fork of the previous [https://github.com/reorg/pg\\_reorg](https://github.com/reorg/pg_reorg) project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

#### Note

Only superusers can use the utility.

#### Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

### Installation

On Linux systems, *pg\_repack* is provided together with Postgres Pro Enterprise as a separate pre-built package `pg-repack-ent-16` and requires the `postgrespro-ent-16-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 17](#). On Windows systems, *pg\_repack* is automatically installed as part of Postgres Pro.

Once you have *pg\_repack* installed, load the *pg\_repack* extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove *pg\_repack* from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of *pg\_repack*, just drop the old version from the database as explained above and install the new version.

### Options

#### Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the *pg\_repack* extension is not installed will be skipped.

`-t table`  
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-I table`  
`--parent-table=table`

Reorganize both the specified table(s) and its inheritors. Multiple table hierarchies may be reorganized by writing multiple `-I` switches.

`-c schema`  
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`  
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`  
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`  
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`  
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`  
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`  
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`  
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`  
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`

`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration and `--no-kill-backend` option is not specified, `pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-D`

`--no-kill-backend`

Skip repacking a table if the lock cannot be taken for duration specified in `--wait-timeout`, instead of cancelling conflicting queries. The default is `false`.

`-Z`

`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

`-k`

`--no-superuser-check`

Skip the superuser checks in the client. This setting is useful for using `pg_repack` on platforms that support running it as non-superusers.

`-C`

`--exclude-extension`

Skip tables that belong to the specified extension(s). Some extensions may heavily depend on such tables at planning time etc.

`--switch-threshold`

Switch tables when that many tuples are left in the log table. This setting can be used to avoid the inability to catch up with write-heavy tables.

## Connection Options

Options to connect to servers. You cannot use `--all` and `--dbname` or `--table` or `--parent-table` together.

`-a`

`--all`

Reorganize all databases.

`[-d] dbname`

`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`

`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`

`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

```
-U username
--username=username
```

User name to connect as.

```
-w
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-W` to avoid the extra connection attempt.

## Generic Options

```
-e
--echo
```

Echo the commands that `pg_repack` generates and sends to the server.

```
-E level
--elevel=level
```

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

```
--help
```

Show help about `pg_repack` command line arguments, and exit.

```
-V
--version
```

Print the `pg_repack` version and exit.

## Environment

```
PGDATABASE
PGHOST
PGPORT
PGUSER
```

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 37.15](#)).

## Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

## Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
```

```
There is a mismatch between the pg_repack binary and the database library  
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
```

```
The SQL extension found in the database does not match the version required by the  
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
```

The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.

Define a PRIMARY KEY or a UNIQUE constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last BEFORE trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

```
ERROR: Another pg_repack command may be running on the table. Please try again later.
```

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

```
WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous
pg_repack on the table which was interrupted. Please use DROP INDEX
"schema"."index_xxxxx" to remove this index and try again.
```

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

## Restrictions

`pg_repack` comes with the following restrictions.

Temporary tables

`pg_repack` cannot reorganize temporary tables.

GiST indexes

`pg_repack` cannot cluster tables by GiST indexes.

#### DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

## I.3. Additional Postgres Pro Server Applications

This section covers additional Postgres Pro Enterprise server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Enterprise distribution.

## mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics

### Synopsis

```
mamonsu agent [agent_action]

mamonsu bootstrap -M mamonsu_user [-c | --config] [-x | --create-extensions] [connection_options]

mamonsu export {template | config} filename [export_options]

mamonsu report [report_options] [connection_options]

mamonsu tune [tuning_options] [connection_options]

mamonsu upload [upload_options]

mamonsu zabbix dashboard upload template_name

mamonsu zabbix {template | host | hostgroup} server_action

mamonsu zabbix item {error | lastvalue | lastclock} host_id

mamonsu zabbix version

mamonsu [-c | --config] [-d | --daemonize]

mamonsu --version

mamonsu --help
```

### Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

### Installation and Setup

#### Important

Before you start installation, attentively read [Compatibility Considerations](#).

To use `mamonsu`, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 17](#) and [Section 18.2](#) for Postgres Pro installation and setup instructions, respectively.

### Note

While `mamonsu` can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

`mamonsu` is provided with Postgres Pro Enterprise as a separate pre-built package `mamonsu` (for the detailed installation instructions, see [Chapter 17](#)). Once you have installed `mamonsu`, complete the following steps to set up metrics collection:

#### 1. Optionally, bootstrap `mamonsu`

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

In this step, the `bootstrap` command sets the `mamonsu` user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

`bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of `bootstrap`:

1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see [Connection Parameters](#).
2. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap
```

This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

In the following example, `bootstrap` options are passed explicitly.

1. Create a non-privileged database user for `mamonsu`. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
GRANT pg_monitor TO mamonsu_user;
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/agent.conf -d
mamonsu_database -U postgres --host myhost --port 5432
```

For details of the options `-M`, `-x` and `-c`, see [bootstrap](#). For details of other options, see [Connection Options](#). This command will create monitoring functions in the `mamonsu_database` and grant the right to execute them to `mamonsu_user`. The `pg_buffercache` extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

As a result, a superuser connection is no longer required. Note that `mamonsu` also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for `mamonsu` to work.

## 2. Configure mamonsu

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

### Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

## 3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

### Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

## Command-Line Reference

### agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get metric_name`

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display `mamonsu` version.

### bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
                  [-c[ config_file] | --config[=config_file]]
                  [-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

**-M**

Specify a non-privileged user that will own all mamonsu processes.

```
-c config_file
--config=config_file
```

Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through `connection_options`.

Default: `/etc/mamonsu/agent.conf`

```
-x
--create-extensions
```

Create auxiliary extensions. The `pg_buffercache` extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the `pgpro_stats` extension and grant the right to execute them to the `mamonsu` user.

```
connection_options
```

Provide optional *command-line connection parameters*.

## export

Syntax:

```
mamonsu export config filename.conf  [--add-plugins=plugin_directory]
mamonsu export template filename.xml  [--add-plugins=plugin_directory]
   [--template-name=template_name]
   [--application=application_name]
   [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

```
--add-plugins=plugin_directory
```

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

```
--template-name=template_name
```

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

```
--application=application_name
```

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

```
--old-zabbix
```

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

**export zabbix-parameters**

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
   [--plugin-type={pg | sys | all}]
   [--pg-version=version]
   [--config=config_file]
```

Export metrics configuration for use with the native [Zabbix agent](#). The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=version`

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

**export zabbix-template**

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
   [--plugin-type={pg | sys | all}]
   [--template-name=template_name]
   [--application=application_name]
   [--config=config_file]
   [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

## report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

*connection\_options*

Provide optional *command-line connection parameters*.

## tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
             [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune *pgbadger* parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

*connection\_options*

Provide optional *command-line connection parameters*.

## upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

### **zabbix dashboard upload**

Syntax:

```
mamonsu dashboard upload template_name
```

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

### **zabbix item**

Syntax:

```
mamonsu zabbix item {error | lastvalue | lastclock } host_name
```

View the specified property of the latest metrics data received by Zabbix for the specified host.

### **zabbix version**

Syntax:

```
mamonsu zabbix version
```

Get the version of the Zabbix server that mamonsu is connected to.

### **zabbix host**

Syntax:

```
mamonsu zabbix host list
mamonsu zabbix host show host_name
mamonsu zabbix host id host_name
mamonsu zabbix host delete host_id
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id
```

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **zabbix hostgroup**

Syntax:

```
mamonsu zabbix hostgroup list
mamonsu zabbix hostgroup show hostgroup_name
mamonsu zabbix hostgroup id hostgroup_name
```

```
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **zabbix template**

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **[--config] [--daemonize]**

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

```
-c config_file
--config=config_file
```

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

```
-d
--daemonize
```

Run in the background. Without it, mamonsu will run in the foreground.

### **--version**

Syntax:

```
mamonsu --version
```

Display mamonsu version.

### **--help**

Syntax:

```
mamonsu --help
```

Display mamonsu command-line help.

### **Connection Options**

*connection\_options* provide command-line connection parameters for the target Postgres Pro cluster. *connection\_options* can be `--host`, `--port`, `--dbname (-d)`, `--username (-U)`, and `--password (-W)`. The `--dbname` option should specify the *mamonsu\_database* created for monitoring purposes. Note that the `--username (-U)` option must specify a superuser that can access the cluster.

If you omit *connection\_options*, mamonsu checks the configuration file for the needed settings.

## Zabbix Server Actions

Using `mamonsu`, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object\_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show object_name`

Display the details about the specified template, host, or host group.

`id object_name`

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete object_id`

Delete the object with the specified ID.

`create hostgroup_name`

`create host_name hostgroup_id template_id mamonsu_address`

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

## Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

All parameters must be specified in the `parameter = value` format.

### Connection Parameters

#### [postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the `mamonsu` user set in `bootstrap`, or a superuser if `bootstrap` was not run.

Default: postgres

password

The password for the specified user.

database

The database to connect to for metrics collection.

Default: postgres

host

The server address to connect to.

Default: localhost

port

The port to connect to.

Default: 5432

application\_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: mamonsu

query\_timeout

[statement\\_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

Alternatively you can specify environment variables rather than the configuration parameters. The following environment variables can be used: PGUSER, PGPASSWORD, PGHOST, PGDATABASE, PGPORT, and PGAPPNAME. See [Section 37.15](#) for their meaning.

#### [system]

The [system] section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to True or False, respectively.

Default: True

#### [zabbix]

The [zabbix] section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metrics data to the Zabbix server if set to True or False, respectively.

Default: True

client

The name of the Zabbix host.

address

The address of the Zabbix server.

Default: 127.0.0.1

port

The port of the Zabbix server.

Default: 10051

timeout

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

#### [agent]

The [agent] section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

enabled

Enables/disables metrics collection from the command line using the agent command.

Default: True

host

The address of the system on which mamonsu is running.

Default: 127.0.0.1

port

The port on which mamonsu is running.

Default: 10052

#### [sender]

The [sender] section controls the queue size of the data to be sent to the Zabbix server:

queue

The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

### Logging Parameters

#### [metric\_log]

The [metric\_log] section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

enabled

Enables/disables storing the collected metrics data in a text file. If this option is set to True, mamonsu creates the localhost.log file for storing metric values.

Default: False

directory

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

`max_size_mb`

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

### [log]

The `[log]` section specifies logging settings for `mamonsu` and can contain the following parameters:

`file`

Specifies the log filename, which can be preceded by the full path.

`level`

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

`format`

The format of the logged data.

Default: `[% (levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

## Plugin Parameters

### [plugins]

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to `mamonsu` after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called “Individual Plugin Sections”](#).

## Individual Plugin Sections

All built-in plugins are installed along with `mamonsu`. To configure a built-in plugin you should find a corresponding section below the `Individual Plugin Sections` heading and edit its parameter values:

`enabled`

Enables/disables using built-in plugins if set to `True` or `False`, respectively. These values are case-sensitive.

Default: False

interval

Specifies the plugin operation interval, in seconds. The parameter is set with an integer specifying the plugin operation interval in seconds. You can set different intervals for different plugins. For plugins that collect PostgreSQL/ Postgres Pro metrics, for example, autovacuum, checkpoint, etc., this is the interval within which mamonsu accesses the Postgres Pro instance for metrics collection. For system plugins, for example, diskstats, memory, etc., this is the interval within which the operating system is accessed. For service plugins, for example, agentapi, logsender, zbxsender, this is the interval within which their functions are called. Note that the `interval` parameter of the `zbxsender` plugin is associated with the `timeout` parameter of the `[zabbix]` section. The maximum Zabbix server response timeout greater than the plugin operation interval may cause misbehavior of the `zbxsender` plugin: the plugin restarts with an error message if the connection or data transfer require longer time than the value specified in the `interval` parameter.

Default: 60

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

#### **[preparedtransaction]**

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION](#) and [Section 57.17](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

#### **[pgprobackup]**

This plugin uses [pg\\_probackup](#) to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified `back-up_directory`.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

## Usage

### Collecting and Viewing Metrics Data

Once started, `mamonsu` begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]          7921004544      1564570818
system.memory[swap_cache]      868352      1564570818
pgsql.connections[idle]        6.0        1564570818
pgsql.archive_command[failed_trying_to_archive] 0      1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where `metric_name` is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/manual>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called “Logging Parameters”](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

### Adding Custom Plugins

You can extend `mamonsu` with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

### Tuning Postgres Pro and System Configuration

Based on the collected metrics data, `mamonsu` can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

## Managing Zabbix Server Settings from the Command Line

`mamonsu` enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
  - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
  - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host\_name* is the name of the host, *hostgroup\_id* and *template\_id* are the unique IDs returned in the previous step, and *mamonsu\_address* is the IP address of the system on which `mamonsu` runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

## Exporting Metrics for Native Zabbix Agent

Using `mamonsu`, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

### Important

To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by `mamonsu` using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:  

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).
2. Generate a template for the native Zabbix agent:  

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).
3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
  - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
  - For `{$PG_PATH}`, specify `psql` installation directory.

## Compatibility Considerations

If you want to upgrade `mamonsu` to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:
  1. Install the new version of `mamonsu`.
  2. Generate a new template for the Zabbix server.
  3. If you performed a bootstrap using the previous version of `mamonsu`, run the `bootstrap` command again.
  4. Upload the new template to the Zabbix server.
  5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
  6. Create a new host for the same system and link the new template to it.
  7. Restart `mamonsu`. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.
- If you do not need to retain the collected data, do the following:
  1. Install the new version of `mamonsu`.
  2. Generate a new template for the Zabbix server.

3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
4. Upload the new template to the Zabbix server.
5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

## pgpro\_controldata

`pgpro_controldata` — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

### Synopsis

```
pgpro_controldata [option...]
```

### Description

`pgpro_controldata` prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

`pgpro_controldata` also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

`pgpro_controldata` is provided with Postgres Pro Enterprise as a separate pre-built package `pgpro-controldata` (for the detailed installation instructions, see [Chapter 17](#)).

### Options

`pgpro_controldata` accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like [pg\\_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

#### General-Purpose

`-B`  
`--bindir`  
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`  
`--pgdata=datadir`  
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`  
`--version`  
Print the `pgpro_controldata` version, then exit.

`-?`  
`--help`  
Show help about `pgpro_controldata` command-line arguments, then exit.

#### Compatibility-Related

`-C`  
`--compatibility-check`  
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`

`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`

`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

## Environment

`PGDATA`

Default data directory location

`PG_COLOR`

Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## See Also

[pg\\_controldata](#)

## pg\_integrity\_check

`pg_integrity_check` — calculate and validate checksums for controlled files (certified edition only)

### Synopsis

```
pg_integrity_check [connection-option...] [-s | --system] [-u | --user] [-c | --catalog] [-o | --output]
[-l filename | --log=filename] [--syslog] [-D datadir] [-C filename] [-v | --verbose] [-? | --help]
```

### Description

`pg_integrity_check` is a utility provided with Postgres Pro Enterprise that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `-s`, `-u`, or `-c` for read-only files, additional files, or system catalog tables, respectively.

If you use the `-o` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `-o` option together with the `-s` option, since a checksum for read-only files cannot be overwritten.

If you omit the `-o` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see [Section 33.2](#).

### Options

*connection-options*

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `-c` option. For detailed description of connection options, see [psql](#).

`-s`  
`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`  
`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`  
`--catalog`

Validate checksums for system catalog tables. For the `-c` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

`-o`  
`--output`

Recalculate checksums and write it into a file.

`-l filename`  
`--log=filename`

Write checksum validation results into a log file.

`--syslog`

Write checksum validation results into the syslog.

`-D datadir`

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `-u` option.

`-C filename`

The absolute path to the configuration file used for integrity checks of system catalog tables of the selected database. If used with the `-o` option, `pg_integrity_check` writes into the specified file. If no other option is used, `pg_integrity_check` checks data against the specified file.

`-v`

`--verbose`

Print debugging information, including checksum values.

`-?`

`--help`

Print command-line help.

## Return Values

0 — checksums are calculated or validated successfully.

1 — an error occurred during the initial checksum calculation for read-only files.

2 — checksum validation revealed changes in one or more of the controlled objects.

3 — an unexpected error occurred during checksum validation.

## Examples

Compute checksums for additional files and write them into the `share/security/_var_lib_pgpro_ent-16_data.user.conf` configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/ent-16/data
```

Check integrity of all controlled objects in the `postgres` database on behalf of the `postgres` user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/ent-16/data -d postgres -h localhost -p  
5432 -U postgres
```

## I.4. Third-Party Server Applications

This section covers third-party server-related applications. They are typically run on the host where the database server resides.

## pgbouncer

pgbouncer — a Postgres Pro connection pooler

### Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

### Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

#### Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

#### Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

#### Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

### Quick Start

pgbouncer is provided with Postgres Pro Enterprise as a separate pre-built package `pgbouncer` (for the detailed installation instructions, see [Chapter 17](#)). Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch `pgbouncer`:

```
$ pgbouncer -d pgbouncer.ini
```

### Note

The above command does not work on Windows systems. Instead, `pgbouncer` must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to `pgbouncer` instead of directly to the PostgreSQL server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage `pgbouncer` by connecting to the special administration database `pgbouncer` and issuing `SHOW HELP`; to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

## Options

`-d`, `--daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

### Note

Does not work on Windows, `pgbouncer` needs to run as service there.

`-R, --reboot`

### Note

This option is deprecated. Instead of this option use a rolling restart with multiple pgbouncer processes listening on the same port using `so_reuseport` instead.

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

### Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

## Admin Console

The console is available by connecting as normal to the database pgbouncer:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this.

## Show Commands

The `SHOW` commands output information. Each command is described below.

**SHOW STATS**

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

total\_xact\_count

Total number of SQL transactions pooled by pgbouncer.

total\_query\_count

Total number of SQL queries pooled by pgbouncer.

total\_received

Total volume in bytes of network traffic received by pgbouncer.

total\_sent

Total volume in bytes of network traffic sent by pgbouncer.

total\_xact\_time

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

total\_query\_time

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

total\_wait\_time

Time spent by clients waiting for a server, in microseconds. Updated when a client connection is assigned a backend connection.

avg\_xact\_count

Average transactions per second in last stat period.

avg\_query\_count

Average queries per second in last stat period.

avg\_recv

Average received (from clients) bytes per second.

avg\_sent

Average sent (to clients) bytes per second.

avg\_xact\_time

Average transaction duration, in microseconds.

avg\_query\_time

Average query duration, in microseconds.

avg\_wait\_time

Average time spent by clients waiting for a server that were assigned a backend connection within the current `stats_period`, in microseconds (average per second within that period).

#### **SHOW STATS\_TOTALS**

Subset of `SHOW STATS` showing the total values (`total_`).

#### **SHOW STATS\_AVERAGES**

Subset of `SHOW STATS` showing the average values (`avg_`).

#### **SHOW TOTALS**

Like `SHOW STATS` but aggregated across all databases.

#### **SHOW SERVERS**

`type`

S, for server.

`user`

User name pgbouncer uses to connect to server.

`database`

Database name.

`state`

State of the pgbouncer server connection, one of `active`, `idle`, `used`, `tested`, `new`, `active_cancel`, or `being_canceled`.

`addr`

IP address of Postgres Pro server.

`port`

Port of Postgres Pro server.

`local_addr`

Connection start address on local machine.

`local_port`

Connection start port on local machine.

`connect_time`

When the connection was made.

`request_time`

When last request was issued.

`wait`

Not used for server connections.

`wait_us`

Not used for server connections.

`close_needed`

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.

`ptr`

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote\_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

application\_name

A string containing the `application_name` set on the linked client connection, or empty if this is not set, or if there is no linked connection.

#### **SHOW CLIENTS**

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of `active`, `waiting`, `active_cancel_req`, or `waiting_cancel_req`.

addr

IP address of the client.

port

Source port of the client.

local\_addr

Connection end address on local machine.

local\_port

Connection end port on local machine.

connect\_time

Timestamp of connect time.

request\_time

Timestamp of latest client request.

wait

Current waiting time in seconds.

wait\_us

Microsecond part of the current waiting time.

`close_needed`

Not used for clients.

`ptr`

Address of internal object for this connection. Used as unique ID.

`link`

Address of server connection the client is paired with.

`remote_pid`

Process ID, in case client connects over Unix socket and OS supports getting it.

`tls`

A string with TLS connection information, or empty if not using TLS.

`application_name`

A string containing the `application_name` set by the client for this connection, or empty if this is not set.

#### **SHOW POOLS**

A new pool entry is made for each couple of (database, user).

`database`

Database name.

`user`

User name.

`cl_active`

Client connections that are either linked to server connections or are idle with no queries waiting to be processed.

`cl_waiting`

Client connections that have sent queries but have not yet got a server connection.

`cl_active_cancel_req`

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

`cl_waiting_cancel_req`

Client connections that have not forwarded query cancellations to the server yet.

`sv_active`

Server connections that are linked to a client.

`sv_active_cancel`

Server connections that are currently forwarding a cancel request.

`sv_being_canceled`

Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.

sv\_idle

Server connections that are unused and immediately usable for client queries.

sv\_used

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

sv\_tested

Server connections that are currently running either `server_reset_query` or `server_check_query`.

sv\_login

Server connections currently in the process of logging in.

maxwait

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

maxwait\_us

Microsecond part of the maximum waiting time.

pool\_mode

The pooling mode in use.

#### **SHOW PEER\_POOLS**

A new `peer_pool` entry is made for each configured peer.

database

ID of the configured peer entry.

cl\_active\_cancel\_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl\_waiting\_cancel\_req

Client connections that have not forwarded query cancellations to the server yet.

sv\_active\_cancel

Server connections that are currently forwarding a cancel request.

sv\_login

Server connections currently in the process of logging in.

#### **SHOW LISTS**

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free\_clients

Count of free clients.

used\_clients

Count of used clients.

login\_clients

Count of clients in login state.

free\_servers

Count of free servers.

used\_servers

Count of used servers.

dns\_names

Count of DNS names in the cache.

dns\_zones

Count of DNS zones in the cache.

dns\_queries

Count of in-flight DNS queries.

dns\_pending

Not used.

#### **SHOW USERS**

name

The user name.

pool\_mode

The user's override `pool_mode`, or `NULL` if the default will be used instead.

#### **SHOW DATABASES**

name

Name of configured database entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.

database

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override `pool_mode`, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

`paused`

1 if this database is currently paused, else 0.

`disabled`

1 if this database is currently disabled, else 0.

#### SHOW PEERS

`peer_id`

ID of the configured peer entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`pool_size`

Maximum number of server connections that can be made to this peer.

#### SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

#### Note

This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

`fd`

File descriptor numeric value.

`task`

One of `pooler`, `client` or `server`.

`user`

User of the connection using the FD.

`database`

Database of the connection using the FD.

`addr`

IP address of the connection using the FD, `unix` if a Unix socket is used.

`port`

Port used by the connection using the FD.

`cancel`

Cancel key for this connection.

`link`

File descriptor for corresponding server/client. `NULL` if idle.

#### **SHOW SOCKETS, SHOW ACTIVE\_SOCKETS**

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

#### **SHOW CONFIG**

Show the current configuration settings, one per row, with the following columns:

`key`

Configuration variable name.

`value`

Configuration value.

`default`

Configuration default value.

`changeable`

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

#### **SHOW MEM**

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

#### **SHOW DNS\_HOSTS**

Show host names in DNS cache.

hostname

Host name.

ttl

How many seconds until next lookup.

addrs

Comma separated list of addresses.

#### **SHOW DNS\_ZONES**

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

#### **SHOW VERSION**

Show the pgbouncer version string.

#### **SHOW STATE**

Show the pgbouncer state settings. Current states are active, paused and suspended.

### **Process Controlling Commands**

#### **PAUSE [db]**

pgbouncer tries to disconnect from all servers. Disconnecting each server connection waits for that server connection to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all server connections have been disconnected. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

#### **DISABLE db**

Reject all new client connections on the given database.

#### **ENABLE db**

Allow new client connections after a previous `DISABLE` command.

#### **RECONNECT db**

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed,

because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimas-ter replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

**KILL *db***

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

**SUSPEND**

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

**RESUME [*db*]**

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

**SHUTDOWN**

The pgbouncer process will exit.

**RELOAD**

The pgbouncer process will reload its configuration files and update changeable settings. This includes the main configuration file as well as the files specified by the settings `auth_file` and `auth_hba_file`.

pgbouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

**WAIT\_CLOSE [*db*]**

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

**Other Commands****SET *key* = *arg***

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

**Signals**

`SIGHUP`

Reload config. Same as issuing the command `RELOAD` on the console.

**SIGINT**

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

**SIGTERM**

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

**SIGUSR1**

Same as issuing `PAUSE` on the console.

**SIGUSR2**

Same as issuing `RESUME` on the console.

**Libevent Settings**

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, libevent displays the kernel notification method that it uses.

**pgbouncer.ini Configuration File**

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

**Generic Settings****logfile**

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation, `kill -HUP` or on console `RELOAD;` should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

**pidfile**

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

**listen\_addr**

Specifies a list (comma-separated) of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

**listen\_port**

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

#### `unix_socket_dir`

Specifies the location for Unix sockets. Applies to both the listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with @ specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (-R) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: /tmp (empty on Windows)

#### `unix_socket_mode`

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

#### `unix_socket_group`

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

#### `user`

If set, specifies the Unix user to change to after startup. Works only if pgbouncer is started as root or if it's already running as the given user.

Not supported on Windows.

Default: not set

#### `pool_mode`

Specifies when a server connection can be reused by other clients.

##### `session`

Server is released back to pool after client disconnects. Default.

##### `transaction`

Server is released back to pool after transaction finishes.

##### `statement`

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

#### `max_client_conn`

Maximum number of client connections allowed.

When this setting is increased, then the file descriptor limits in the operating system might also have to be increased. Note that the number of file descriptors potentially used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should never be reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

#### `default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

#### `min_pool_size`

Add more server connections to pool if below this number. Improves the behavior when the normal load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

#### `reserve_pool_size`

How many additional connections to allow to a pool (see `reserve_pool_timeout`). The 0 value disables this parameter.

Default: 0 (disabled)

#### `reserve_pool_timeout`

If a client has not been serviced in this time, `pgbouncer` enables use of additional connections from the reserve pool. The 0 value disables this parameter. [seconds]

Default: 5.0

#### `max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the `pgbouncer` database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

#### `max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the `pgbouncer` user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

### server\_round\_robin

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is a round-robin system behind a database address (TCP, DNS, or host list), then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

### track\_extra\_parameters

By default, pgbouncer tracks `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings` and `application_name` parameters per client. To allow other parameters to be tracked, they can be specified here, so that pgbouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list (e.g. `default_transaction_read-only, IntervalStyle`)

### Note

Most parameters cannot be tracked this way. The only parameters that can be tracked are ones that Postgres Pro reports to the client. Postgres Pro has [an official list of parameters that it reports to the client](#). Postgres Pro extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing parameters that Postgres Pro does not report. Notably Citus 12.0+ causes PostgreSQL to also report `search_path`.

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `track_extra_parameters`. However, it's not possible to include `options` itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: `IntervalStyle`

### ignore\_startup\_parameters

By default, pgbouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that pgbouncer knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list (e.g. `options,extra_float_digits`).

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It's even possible to include `options` itself in `ignore_startup_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

Default: empty

### peer\_id

The peer ID used to identify this pgbouncer process in a group of pgbouncer processes that are peered together. The `peer_id` value should be unique within a group of peered pgbouncer processes. When set to 0, pgbouncer peering is disabled. See also [\[peers\] Section](#) for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

`disable_pgexec`

Disable the Simple Query protocol (PQexec). Unlike the Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously, this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only at the start of a connection. If `application_name` is later changed with `SET`, `pgbouncer` does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make `pgbouncer` use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for `service_name`.

`stats_period`

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

### Authentication Settings

`pgbouncer` handles its own client authentication and has its own database of users. These settings control this.

`auth_type`

How to authenticate users.

`cert`

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

`md5`

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

`scram-sha-256`

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client

but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

#### plain

The clear-text password is sent over the wire. Deprecated.

#### trust

No authentication is done. The user name must still exist in `auth_file`.

#### any

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

#### hba

The actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods for different access paths, for example: connections over Unix socket use `peer` authentication method, connections over TCP must use TLS.

#### pam

Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name reported to PAM is `pgbouncer`. `pam` is not supported in the HBA configuration file.

#### auth\_hba\_file

HBA configuration file to use when `auth_type` is `hba`.

Default: not set

#### auth\_file

The name of the file to load user names and passwords from. See [the section called “Authentication File Format”](#) for details.

Most authentication types (see `auth_type`) require that either `auth_file` or `auth_user` be set; otherwise there would be no users defined.

Default: not set

#### auth\_user

If `auth_user` is set, then any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database, using `auth_user`. The password of `auth_user` will be taken from `auth_file`. (If `auth_user` does not require a password, then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

#### auth\_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

**Default:** `SELECT username, passwd FROM pg_shadow WHERE username=$1`

`auth_dbname`

Database name in the [\[databases\] section](#) to be used for authentication purposes. This option can be either global or overridden in the connection string if this parameter is specified.

### Log Settings

`syslog`

Toggles syslog on/off. On Windows, the event log is used instead.

**Default:** 0

`syslog_ident`

Under what name to send logs to syslog.

**Default:** `pgbouncer` (program name)

`syslog_facility`

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

**Default:** `daemon`

`log_connections`

Log successful logins.

**Default:** 1

`log_disconnections`

Log disconnections with reasons.

**Default:** 1

`log_pooler_errors`

Log error messages the pooler sends to clients.

**Default:** 1

`log_stats`

Write aggregated statistics into the log, every [stats\\_period](#). This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

**Default:** 1

`verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. For example, using `-v -v` on the command line is the same as `verbose=2`.

**Default:** 0

### Console Access Control

`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when [auth\\_type](#) is `any`, in which case any user name is allowed in as admin.

**Default:** empty

#### stats\_users

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

### Connection Sanity Checks, Timeouts

#### server\_reset\_query

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress, so the value should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL`, which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, because in that mode, clients must not use any session-based features, since each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL`

#### server\_reset\_query\_always

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

#### server\_check\_delay

How long to keep released connections available for immediate re-use, without running `server_check_query` on it. If 0 then the query is always run.

Default: 30.0

#### server\_check\_query

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `select 1`

#### server\_fast\_close

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a

configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

#### `server_lifetime`

The pooler will close an unused (not currently linked to any client connection) server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

#### `server_idle_timeout`

If a server connection has been idle more than this many seconds it will be closed. If 0 then timeout is disabled. [seconds]

Default: 600.0

#### `server_connect_timeout`

If connection and login don't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

#### `server_login_retry`

If login to the server failed, because of failure to connect or from authentication, the pooler waits this much before retrying to connect. During the waiting interval, new clients trying to connect to the failing server will get an error immediately without another connection attempt. [seconds]

The purpose of this behavior is that clients don't unnecessarily queue up waiting for a server connection to become available if the server is not working. However, it also means that if a server is momentarily failing, for example during a restart or if the configuration was erroneous, then it will take at least this long until the pooler will consider connecting to it again. Planned events such as restarts should normally be managed using the `PAUSE` command to avoid this.

Default: 15.0

#### `client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

#### `autodb_idle_timeout`

If the automatically created (via `"*`") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

#### `dns_max_ttl`

How long DNS lookups can be cached. The actual DNS TTL is ignored. [seconds]

Default: 15.0

#### `dns_nxdomain_ttl`

How long DNS errors and `NXDOMAIN` DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, its connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not pgbouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

### TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate pgbouncer uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. The default mode is `prefer`.

`disable`

Plain TCP. TLS is not even requested from the server.

`prefer`

TLS connection is always requested first from Postgres Pro. If refused, the connection will be established over plain TCP. Server certificate is not validated. Default.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

### **Dangerous Timeouts**

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. The 0 value disables this parameter. If this is disabled, clients will be queued indefinitely. [seconds]

This setting is used to prevent unresponsive servers from grabbing up connections. It also helps when the server is down or rejects connections for any reason.

Default: 120.0

`cancel_wait_timeout`

Maximum time cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. 0 disables. If this is disabled, cancel requests will be queued indefinitely. [seconds]

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Default: 10.0

#### `client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

#### `idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

#### `suspend_timeout`

How long to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed. [seconds]

Default: 10

### Low-Level Network Settings

#### `pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

#### `max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. The full result set can be larger.

Default: 2147483647

#### `listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in the queue. When the queue is full, further new connections are dropped.

Default: 128

#### `sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

#### `so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

To make sure query cancellations keep working, you should set up pgbouncer peering between the different pgbouncer processes. For details see the [peer\\_id configuration option](#) and the [\[peers\] configuration section](#). There's also an example that uses peering and `so_reuseport` in the [Examples section](#).

Default: 0

`tcp_defer_accept`

Sets the `TCP_DEFER_ACCEPT` socket option; see `man 7 tcp` for details. (This is a Boolean option: 1 means enabled. The actual value set if enabled is currently hardcoded to 45 seconds.)

This is currently only supported on Linux.

Default: 1 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **`tcp_keepidle=7200`**, **`tcp_keepintvl=75`**, **`tcp_keepcnt=9`**. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

### Section [databases]

The section `[databases]` defines the names of the databases that clients of pgbouncer can connect to and specifies where those connections will be routed. The section contains `key=value` lines like

```
dbname = connection string
```

where the key will be taken as a database name and the value as a connection string, consisting of `key=value` pairs of connection parameters, described below (similar to `libpq`, but the actual `libpq` is not used and the set of available features is different).

Example:

```
foodb = host=host1.example.com port=5432
```

```
bardb = host=localhost dbname=bazdb
```

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `"` is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

\* acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to `pgbouncer` specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in a round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

A comma-separated list of host names or addresses can be specified. In that case, connections are made in a round-robin manner. (If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. This is an implementation dependency that is subject to change.) Note that in a list, all hosts must be available at all times: there are no mechanisms to skip unreachable hosts or to select only available hosts from a list or similar. (This is different from what a host list in `libpq` means.) Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` for how clients are assigned to already established server connections.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise pgbouncer logs into the destination database with the client user name, meaning that there will be one pool per user.

password

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

auth\_user

Override of the global `auth_user` setting, if specified.

pool\_size

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

min\_pool\_size

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

reserve\_pool

Set additional connections for this database. If not set, `reserve_pool_size` is used.

connect\_query

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

pool\_mode

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

max\_db\_connections

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

client\_encoding

Ask specific `client_encoding` from server.

datestyle

Ask specific `datestyle` from server.

timezone

Ask specific `timezone` from server.

### Section [users]

This section contains `key=value` lines like

```
user1 = settings
```

where the key will be taken as a user name and the value as a list of configuration settings specific for this user.

Example:

```
user1 = pool_mode=session
```

Only a few settings are available here.

pool\_mode

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

### Section [peers]

This section defines the peers that pgbouncer can forward cancellation requests to and where those cancellation requests will be routed.

pgbouncer processes can be peered together in a group by defining a `peer_id` value and a `[peers]` section in the configs of all the pgbouncer processes. These pgbouncer processes can then forward cancellation requests to the process that it originated from. This is needed to make cancellations work when multiple pgbouncer processes (possibly on different servers) are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains key=value lines like

```
peer_id = connection string
```

where the key will be taken as a `peer_id` and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
1 = host=host1.example.com
2 = host=/tmp/pgbouncer-2 port=5555
```

### Note

For peering to work, the `peer_id` of each pgbouncer process in the group must be unique within the peered group. And the `[peers]` section should contain entries for each of those peer IDs. An example can be found in the [Examples](#) section. It is allowed, but not necessary, for the `[peers]` section to contain the `peer_id` of the pgbouncer that the config is for. Such an entry will be ignored, but it is allowed to make config management easier. Because it allows using the exact same `[peers]` section for multiple configs.

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it's not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```

`port`

Default: 6432

`pool_size`

If not set, the `default_pool_size` is used.

#### **Include Directive**

The pgbouncer configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the filename is not an absolute path, it is taken as relative to the current working directory.

#### **Authentication File Format**

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. pgbouncer ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

```
So      user      admin      with      password      1234      will      have      MD5-hashed      password
md545f2603610af569b6155c45067268c6b.
```

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

#### **HBA File Format**

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in [Section 20.1](#).

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.

- **Database field:** Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- **User name field:** Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- **Address field:** Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- **Auth-method field:** Only methods supported by `pgbouncer`'s `auth_type` are supported, plus `peer` and `reject`, but except `any` and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

## Examples

Small example configuration:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database examples:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb

; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

Example of a secure function for `auth_query`:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END; $$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

Example configs for 2 peered `pgbouncer` processes to create a multi-core `pgbouncer` setup using [so\\_reuseport](#).

The config for the first process:

```
[databases]
postgres = host=localhost dbname=postgres
```

```
[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

**The config for the second process:**

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

## pg\_filedump

`pg_filedump` — display formatted contents of a Postgres Pro heap, index, or control file

### Synopsis

```
pg_filedump [option...] [file]
```

### Description

`pg_filedump` is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the [Options](#) section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

### Installation

`pg_filedump` is provided with Postgres Pro Enterprise as a separate pre-built package `pg-file-dump-ent-16` (for the detailed installation instructions, see [Chapter 17](#)).

### Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

`-a`  
Display absolute addresses when formatting. Block header information is always block-relative.

`-b`  
Display binary block images within a range. The option will turn off all formatting options.

`-d`  
Display formatted block content dump. The option will turn off all other formatting options.

`-D attrlist`  
Decode tuples using given comma-separated list of types. The list of supported types:

```
bigint  
bigserial  
bool  
char  
charN — char(n)  
date  
float  
float4  
float8  
int  
json  
macaddr  
name  
numeric  
oid  
real
```

```

serial
smallint
smallserial
text
time
timestamp
timetz
uuid
varchar
varcharN — varchar(n)
xid
xml
~ — ignore all attributes left in a tuple

```

- f  
Display formatted block content dump along with interpretation.
- h  
Display help.
- i  
Display interpreted item details.
- k  
Verify block checksums.
- o  
Do not dump old values.
- R *startblock* [*endblock*]  
Display specific block ranges within the file. Blocks are indexed from 0. *startblock*: block to start at. *endblock*: block to end at. A *startblock* without an *endblock* will format a single block.
- s *segsize*  
Force segment size to *segsize*.
- t  
Dump TOAST files.
- v  
Output additional information about TOAST relations.
- n *segnumber*  
Force segment number to *segnumber*.
- S *blocksize*  
Force block size to *blocksize*.
- x  
Force interpreted formatting of block items as index items.
- y  
Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S blocksize`

Force block size to *blocksize*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

# Appendix J. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

## J.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Enterprise distribution:

- [libpq](#) is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- [ECPG](#) is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. A [list of language interfaces](#) is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

[https://wiki.postgresql.org/wiki/List\\_of\\_drivers](https://wiki.postgresql.org/wiki/List_of_drivers)

## J.2. Administration Tools

There are several administration tools available for Postgres Pro. One of them is PPEM, an integrated administration panel for Postgres Pro Enterprise management. It provides centralized privilege-based access to a unified management and monitoring interface with embedded command line. There are other solutions, e.g. an open-source platform [pgAdmin](#).

## J.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. A list of [procedural languages](#) is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

[https://wiki.postgresql.org/wiki/PL\\_Matrix](https://wiki.postgresql.org/wiki/PL_Matrix)

## J.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in [Appendix F](#). Other extensions are developed independently, like [PostGIS](#). Even Postgres Pro replication solutions can be developed externally. For example, [Slony-I](#) is a popular primary/standby replication solution that is developed independently from the core project. Some extensions are made compatible with Postgres Pro Enterprise, for example, [citius](#). Consult the Postgres Pro Enterprise support team if you want to gain access to such extensions.

## J.5. citus — distributed database and columnar storage functionality

[citus](#) is an extension that is made compatible with Postgres Pro and provides such major functionalities as columnar data storage and distributed OLAP database, which can be used either together or separately.

[citus](#) offers the following benefits:

- Columnar storage with data compression.
- The ability to scale your Postgres Pro installation to a distributed database cluster.
- Row-based or schema-based sharding.
- Parallelized DML operations across cluster nodes.
- Reference tables, which can be accessed locally on each node.
- The ability to execute DML queries on any node, which allows utilizing the full capacity of your cluster for distributed queries.

### J.5.1. Limitations

citus is incompatible with some Postgres Pro Enterprise features, take note of these limitations while arranging your work with the extension:

- citus cannot be used together with [autonomous transactions](#).
- With [enable\\_self\\_join\\_removal](#) set to `on`, query planning will result in an error if the optimizer decides to make the query distributed. Otherwise, the optimizer may form an erroneous distributed query plan and produce incorrect query results. Therefore, it is recommended to set this parameter to `off`.
- [Real-time query replanning](#) and citus should not be used together. If used, the `EXPLAIN ANALYZE` command may operate incorrectly.
- citus cannot operate with [standard\\_conforming\\_strings](#) set to `off`. `citus_columnar` can, but to avoid any errors, it is required to set the configuration parameter to `on` while executing the `CREATE EXTENSION` or `ALTER EXTENSION UPDATE` commands. After the installation or update is completed, you can change the parameter value to `off`, if necessary. The extension will continue to operate correctly.

### J.5.2. Installation

#### J.5.2.1. Installing citus on a Single Node

To enable citus on a single node, complete the following steps:

1. Add `citus` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'citus'
```

If you want to use citus together with other extensions, citus should be the first on the list of `shared_preload_libraries`.

2. Reload the database server for the changes to take effect. To verify that the `citus` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Create the citus extension using the following query:

```
CREATE EXTENSION citus;
```

The `CREATE EXTENSION` command in the procedure above also installs the `citus_columnar` extension. If you want to enable *only* `citus_columnar`, complete the same steps but specify `citus_columnar` instead.

#### J.5.2.2. Installing citus on Multiple Nodes

To enable citus on multiple nodes, complete the following steps on all nodes:

1. Add `citus` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'citus'
```

If you want to use citus together with other extensions, citus should be the first on the list of `shared_preload_libraries`.

2. Set up access permissions to the database server. By default, the database server listens only to clients on `localhost`. Set the `listen_addresses` configuration parameter to `*` to specify all available IP interfaces.
3. Configure client authentication by editing the `pg_hba.conf` file.
4. Reload the database server for the changes to take effect. To verify that the `citus` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

5. Create the citus extension using the following query:

```
CREATE EXTENSION citus;
```

When the above steps have been taken on all nodes, perform the actions below on the coordinator node for worker nodes to be able to connect to it:

1. Register the hostname that worker nodes use to connect to the coordinator node:

```
SELECT citus_set_coordinator_host('coordinator_name', coordinator_port);
```

2. Add each worker node:

```
SELECT * from citus_add_node('worker_name', worker_port);
```

3. Verify that worker nodes are set successfully:

```
SELECT * FROM citus_get_active_worker_nodes();
```

## J.5.3. When to Use citus

### J.5.3.1. Multi-Tenant SaaS Database

Most B2B applications already have the notion of a tenant, customer, or account built into their data model. In this model, the database serves many tenants, each of whose data is separate from other tenants.

`citus` provides full SQL functionality for this workload and enables scaling out your relational database to more than 100,000 tenants. `citus` also adds new features for multi-tenancy. For example, `citus` supports tenant isolation to provide performance guarantees for large tenants, and has the concept of reference tables to reduce data duplication across tenants.

These capabilities allow you to scale out data of your tenants across many computers and add more CPU, memory, and disk resources. Further, sharing the same database schema across multiple tenants makes efficient use of hardware resources and simplifies database management.

`citus` offers the following advantages for multi-tenant applications:

- Fast queries for all tenants.
- Sharding logic in the database rather than the application.
- Hold more data in single-node Postgres Pro.
- Scale out maintaining the SQL functionality.
- Maintain performance under high concurrency.
- Fast metrics analysis across customer base.
- Scale to handle new customer sign-ups.
- Isolate resource usage of large and small customers.

### J.5.3.2. Real-Time Analytics

citus supports real-time queries over large datasets. Commonly these queries occur in rapidly growing event systems or systems with time series data. Example use cases include:

- Analytic dashboards with sub-second response times.
- Exploratory queries on unfolding events.
- Large dataset archival and reporting.
- Analyzing sessions with funnel, segmentation, and cohort queries.

citus parallelizes query execution and scales linearly with the number of worker databases in a cluster. Some advantages of citus for real-time applications are as follows:

- Maintain sub-second responses as the dataset grows.
- Analyze new events and new data in real time.
- Parallelize SQL queries.
- Scale out maintaining the SQL functionality.
- Maintain performance under high concurrency.
- Fast responses to dashboard queries.
- Use one database rather than many on several nodes.
- Rich Postgres Pro data types and extensions.

### J.5.3.3. Microservices

citus supports schema-based sharding, which allows distributing regular database schemas across many computers. This sharding methodology aligns well with typical microservices architecture, where storage is fully owned by the service hence cannot share the same schema definition with other tenants.

Schema-based sharding is an easier model to adopt, create a new schema, and set the `search_path` in your service.

Advantages of using citus for microservices:

- Allows distributing horizontally scalable state across services.
- Transfer strategic business data from microservices into common distributed tables for analytics.
- Efficiently use hardware by balancing services on multiple computers.
- Isolate noisy services to their own nodes.
- Easy to understand sharding model.
- Quick adoption.

### J.5.3.4. Considerations for Use

citus extends Postgres Pro with distributed functionality, but it is not a drop-in replacement that scales out all workloads. A performant citus cluster involves thinking about the data model, tooling, and choice of SQL features used.

A good way to think about tools and SQL features is the following: if your workload aligns with use cases described here and you happen to run into an unsupported tool or query, then there is usually a good workaround.

### J.5.3.5. When citus is Inappropriate

Some workloads do not need a powerful distributed database, while others require a large flow of information between worker nodes. In the first case citus is unnecessary and in the second not generally performant. Below are a few examples when you do not need to use citus:

- You do not expect your workload to ever grow beyond a single Postgres Pro Enterprise node.
- Offline analytics, without the need for real-time data transfer nor real-time queries.
- Analytics apps that do not need to support a large number of concurrent users.
- Queries that return data-heavy ETL results rather than summaries.

## J.5.4. Quick Tutorials

### J.5.4.1. Multi-Tenant Applications

In this tutorial a sample ad analytics dataset is used to demonstrate how you can use citus to power your multi-tenant application.

#### Note

This tutorial assumes that you already have citus installed and running. If not, consult the [Installing citus on a Single Node](#) section to set up the extension locally.

#### J.5.4.1.1. Data Model and Sample Data

This section shows how to create a database for an ad analytics app, which can be used by companies to view, change, analyze, and manage their ads and campaigns (see an [example app](#)). Such an application has good characteristics of a typical multi-tenant system. Data from different tenants is stored in a central database, and each tenant has an isolated view of their own data.

Three Postgres Pro tables to represent this data will be used. To get started, download sample data for these tables:

```
curl https://examples.citusdata.com/tutorial/companies.csv > companies.csv
curl https://examples.citusdata.com/tutorial/campaigns.csv > campaigns.csv
curl https://examples.citusdata.com/tutorial/ads.csv > ads.csv
```

#### J.5.4.1.2. Creating Tables

1. First connect to the citus coordinator using `psql`.

If you are using citus installed as described in the [Installing citus on a Single Node](#) section, the coordinator node will be running on port 9700.

```
psql -p 9700
```

2. Create tables by using the standard Postgres Pro `CREATE TABLE` command:

```
CREATE TABLE companies (  
    id bigint NOT NULL,  
    name text NOT NULL,  
    image_url text,  
    created_at timestamp without time zone NOT NULL,  
    updated_at timestamp without time zone NOT NULL  
);
```

```
CREATE TABLE campaigns (  
    id bigint NOT NULL,  
    company_id bigint NOT NULL,  
    name text NOT NULL,  
    cost_model text NOT NULL,  
    state text NOT NULL,  
    monthly_budget bigint,  
    blacklisted_site_urls text[],
```

```

        created_at timestamp without time zone NOT NULL,
        updated_at timestamp without time zone NOT NULL
    );

CREATE TABLE ads (
    id bigint NOT NULL,
    company_id bigint NOT NULL,
    campaign_id bigint NOT NULL,
    name text NOT NULL,
    image_url text,
    target_url text,
    impressions_count bigint DEFAULT 0,
    clicks_count bigint DEFAULT 0,
    created_at timestamp without time zone NOT NULL,
    updated_at timestamp without time zone NOT NULL
);

```

3. Create primary key indexes on each of the tables just like you would do in Postgres Pro:

```

ALTER TABLE companies ADD PRIMARY KEY (id);
ALTER TABLE campaigns ADD PRIMARY KEY (id, company_id);
ALTER TABLE ads ADD PRIMARY KEY (id, company_id);

```

#### J.5.4.1.3. Distributing Tables and Loading Data

Now you can instruct citus to distribute tables created above across the different nodes in the cluster. To do so, run the [create\\_distributed\\_table](#) function and specify the table you want to shard and the column you want to shard on. In the example below, all the tables are sharded on the `company_id` column.

```

SELECT create_distributed_table('companies', 'id');
SELECT create_distributed_table('campaigns', 'company_id');
SELECT create_distributed_table('ads', 'company_id');

```

Sharding all tables on the `company_id` column allows citus to [co-locate](#) the tables together and allows for features like primary keys, foreign keys, and complex joins across your cluster.

Then you can go ahead and load the downloaded data into the tables using the standard `psql \copy` command. Make sure that you specify the correct file path if you downloaded the file to a different location.

```

\copy companies from 'companies.csv' with csv
\copy campaigns from 'campaigns.csv' with csv
\copy ads from 'ads.csv' with csv

```

#### J.5.4.1.4. Running Queries

After the data is loaded into the tables, you can run some queries. citus supports standard `INSERT`, `UPDATE`, and `DELETE` commands for inserting and modifying rows in a distributed table, which is the typical way of interaction for a user-facing application.

For example, you can insert a new company by running:

```

INSERT INTO companies VALUES (5000, 'New Company', 'https://randomurl/image.png',
    now(), now());

```

If you want to double the budget for all campaigns of the company, run the `UPDATE` command:

```

UPDATE campaigns
SET monthly_budget = monthly_budget*2
WHERE company_id = 5;

```

Another example of such an operation is to run transactions, which span multiple tables. For example, you can delete a campaign and all its associated ads atomically by running:

```
BEGIN;
DELETE FROM campaigns WHERE id = 46 AND company_id = 5;
DELETE FROM ads WHERE campaign_id = 46 AND company_id = 5;
COMMIT;
```

Each statement in a transaction causes round-trips between the coordinator and workers in the multi-node citus. For multi-tenant workloads, it is more efficient to run transactions in distributed functions. The efficiency gains become more apparent for larger transactions, but you can use the small transaction above as an example.

1. First create a function that does the deletions:

```
CREATE OR REPLACE FUNCTION
  delete_campaign(company_id int, campaign_id int)
RETURNS void LANGUAGE plpgsql AS $fn$
BEGIN
  DELETE FROM campaigns
    WHERE id = $2 AND campaigns.company_id = $1;
  DELETE FROM ads
    WHERE ads.campaign_id = $2 AND ads.company_id = $1;
END;
$fn$;
```

2. Next use the [create\\_distributed\\_function](#) function to instruct citus to call the function directly on workers rather than on the coordinator (except on a single-node citus installation, which runs everything on the coordinator). It calls the function on whatever worker holds the [shards](#) for the `ads` and `campaigns` tables corresponding to the `company_id` value.

```
SELECT create_distributed_function(
  'delete_campaign(int, int)', 'company_id',
  colocate_with := 'campaigns'
);
```

```
-- You can run the function as usual
SELECT delete_campaign(5, 46);
```

3. Besides transactional operations, you can also run analytics queries using standard SQL. One interesting query for a company to run is to see details about its campaigns with maximum budget.

```
SELECT name, cost_model, state, monthly_budget
FROM campaigns
WHERE company_id = 5
ORDER BY monthly_budget DESC
LIMIT 10;
```

4. You can also run a join query across multiple tables to see information about running campaigns, which receive the most clicks and impressions.

```
SELECT campaigns.id, campaigns.name, campaigns.monthly_budget,
       sum(impressions_count) AS total_impressions, sum(clicks_count) AS
       total_clicks
FROM ads, campaigns
WHERE ads.company_id = campaigns.company_id
AND ads.campaign_id = campaigns.id
AND campaigns.company_id = 5
AND campaigns.state = 'running'
GROUP BY campaigns.id, campaigns.name, campaigns.monthly_budget
ORDER BY total_impressions, total_clicks;
```

The tutorial above shows how to use citus to power a simple multi-tenant application. As a next step, you can look at the [Multi-Tenant Apps](#) section to see how you can model your own data for multi-tenancy.

### J.5.4.2. Real-Time Analytics

This tutorial demonstrates how to use citus to ingest events data and run analytical queries on that data in human real-time. A sample GitHub events dataset is used to this end in the example.

#### Note

This tutorial assumes that you already have citus installed and running. If not, consult the [Installing citus on a Single Node](#) section to set up the extension locally.

#### J.5.4.2.1. Data Model and Sample Data

This section shows how to create a database for a real-time analytics application. This application will insert large volumes of events data and enable analytical queries on that data with sub-second latencies. In this example, the GitHub events dataset is used. This dataset includes all public events on GitHub, such as `commits`, `forks`, `new issues`, and `comments` on these issues.

Two Postgres Pro tables are used to represent this data. To get started, download sample data for these tables:

```
curl https://examples.citusdata.com/tutorial/users.csv > users.csv
curl https://examples.citusdata.com/tutorial/events.csv > events.csv
```

#### J.5.4.2.2. Creating Tables

To start first connect to the citus coordinator using `psql`.

If you are using citus installed as described in the [Installing citus on a Single Node](#) section, the coordinator node will be running on port 9700.

```
psql -p 9700
```

Then you can create the tables by using the standard Postgres Pro `CREATE TABLE` command:

```
CREATE TABLE github_events
(
    event_id bigint,
    event_type text,
    event_public boolean,
    repo_id bigint,
    payload jsonb,
    repo jsonb,
    user_id bigint,
    org jsonb,
    created_at timestamp
);

CREATE TABLE github_users
(
    user_id bigint,
    url text,
    login text,
    avatar_url text,
    gravatar_id text,
    display_login text
);
```

Next you can create indexes on events data just like you do in Postgres Pro. This example also shows how to create a GIN index to make querying on JSONB fields faster.

```
CREATE INDEX event_type_index ON github_events (event_type);
CREATE INDEX payload_index ON github_events USING GIN (payload jsonb_path_ops);
```

#### J.5.4.2.3. Distributing Tables and Loading Data

Now you can instruct citus to distribute the tables created above across the nodes in the cluster. To do so, you can call the [create\\_distributed\\_table](#) function and specify the table you want to shard and the column you want to shard on. In the example below, all the tables are sharded on the `user_id` column.

```
SELECT create_distributed_table('github_users', 'user_id');
SELECT create_distributed_table('github_events', 'user_id');
```

Sharding all tables on the `user_id` column allows citus to [co-locate](#) the tables together and allows for efficient joins and distributed roll-ups.

Then you can go ahead and load the downloaded data into the tables using the standard `psql \copy` command. Make sure that you specify the correct file path if you downloaded the file to a different location.

```
\copy github_users from 'users.csv' with csv
\copy github_events from 'events.csv' with csv
```

#### J.5.4.2.4. Running Queries

After the data is loaded into the tables, you can run some queries. First check how many users are contained in the distributed database.

```
SELECT count(*) FROM github_users;
```

Now analyze GitHub push events in the data. First compute the number of commits per minute by using the number of distinct commits in each push event.

```
SELECT date_trunc('minute', created_at) AS minute,
       sum((payload->>'distinct_size')::int) AS num_commits
FROM github_events
WHERE event_type = 'PushEvent'
GROUP BY minute
ORDER BY minute;
```

Also, there is a users table. You can also join the users with events and find the top ten users who created the most repositories.

```
SELECT login, count(*)
FROM github_events ge
JOIN github_users gu
ON ge.user_id = gu.user_id
WHERE event_type = 'CreateEvent' AND payload @> '{"ref_type": "repository"}'
GROUP BY login
ORDER BY count(*) DESC LIMIT 10;
```

citus also supports standard `INSERT`, `UPDATE`, and `DELETE` commands for inserting and modifying data. For example, you can update the user display login by running the following command:

```
UPDATE github_users SET display_login = 'no1youknow' WHERE user_id = 24305673;
```

As a next step, you can look at the [Real-Time Apps](#) section to see how you can model your own data and power real-time analytical applications.

#### J.5.4.3. Microservices

This tutorial shows how to use citus as the storage backend for multiple microservices and demonstrates a sample setup and basic operation of such a cluster.

### Note

This tutorial assumes that you already have citus installed and running. If not, consult the [Installing citus on a Single Node](#) section to set up the extension locally.

#### J.5.4.3.1. Distributed Schemas

Distributed schemas are relocatable within a citus cluster. The system can rebalance them as a whole unit across the available nodes, which allows for efficient sharing of resources without manual allocation.

By design, microservices own their storage layer, we do not make any assumptions on the type of tables and data that they will create and store. We, however, provide a schema for every service and assume that they use a distinct role to connect to the database. When a user connects, their role name is put at the beginning of the `search_path`, so if the role matches the schema name, you do not need any application changes to set the correct `search_path`.

Three services are used in the example:

- `user service`
- `time service`
- `ping service`

To start first connect to the citus coordinator using `psql`.

If you are using citus installed as described in the [Installing citus on a Single Node](#) section, the coordinator node will be running on port 9700.

```
psql -p 9700
```

You can now create the database roles for every service:

```
CREATE USER user_service;  
CREATE USER time_service;  
CREATE USER ping_service;
```

There are two ways to distribute a schema in citus:

- Manually by calling the `citus_schema_distribute('schema_name')` function:

```
CREATE SCHEMA AUTHORIZATION user_service;  
CREATE SCHEMA AUTHORIZATION time_service;  
CREATE SCHEMA AUTHORIZATION ping_service;  
  
SELECT citus_schema_distribute('user_service');  
SELECT citus_schema_distribute('time_service');  
SELECT citus_schema_distribute('ping_service');
```

This method also allows you to convert existing regular schemas into distributed schemas.

#### Note

You can only distribute schemas that do not contain distributed and reference tables.

- Alternative approach is to enable the [citus.enable\\_schema\\_based\\_sharding](#) configuration parameter:

```
SET citus.enable_schema_based_sharding TO ON;  
  
CREATE SCHEMA AUTHORIZATION user_service;  
CREATE SCHEMA AUTHORIZATION time_service;  
CREATE SCHEMA AUTHORIZATION ping_service;
```

The parameter can be changed for the current session or permanently in the `postgresql.conf` file. With the parameter set to `ON` all created schemas are distributed by default.

You can list the currently distributed schemas:

```
SELECT * FROM citus_schemas;

schema_name | colocation_id | schema_size | schema_owner
-----+-----+-----+-----
user_service |          5 | 0 bytes | user_service
time_service |          6 | 0 bytes | time_service
ping_service |          7 | 0 bytes | ping_service
(3 rows)
```

#### J.5.4.3.2. Creating Tables

You now need to connect to the citus coordinator for every microservice. You can use the `\c` command to swap the user within an existing `psql` instance.

```
\c citus user_service

CREATE TABLE users (
    id SERIAL PRIMARY KEY,
    name VARCHAR(255) NOT NULL,
    email VARCHAR(255) NOT NULL
);

\c citus time_service

CREATE TABLE query_details (
    id SERIAL PRIMARY KEY,
    ip_address INET NOT NULL,
    query_time TIMESTAMP NOT NULL
);

\c citus ping_service

CREATE TABLE ping_results (
    id SERIAL PRIMARY KEY,
    host VARCHAR(255) NOT NULL,
    result TEXT NOT NULL
);
```

#### J.5.4.3.3. Configure Services

For the purpose of this tutorial a very simple set of services is used. You can obtain them by cloning this public repository:

```
git clone https://github.com/citusdata/citus-example-microservices.git
```

The repository contains the `ping`, `time`, and `user` services. All of them have the `app.py` file, which we run.

```
$ tree
.
├── LICENSE
├── README.md
├── ping
│   ├── app.py
│   ├── ping.sql
│   └── requirements.txt
├── time
│   ├── app.py
│   ├── requirements.txt
│   └── time.sql
└── user
    ├── app.py
    ├── requirements.txt
    └── user.sql
```

Before you run the services, however, edit the `user/app.py`, `ping/app.py`, and `time/app.py` files providing the [connection configuration](#) for your citus cluster:

```
# Database configuration
db_config = {
    'host': 'localhost',
    'database': 'citus',
    'user': 'ping_service',
    'port': 9700
}
```

After making the changes save all modified files and move on to the next step of running the services.

#### J.5.4.3.4. Running the Services

- Change into every app directory and run them in their own `python` environment.

```
cd user
pipenv install
pipenv shell
python app.py
```

Repeat the above for the `time` and `ping` service, after which you can use the API.

- Create some users:

```
curl -X POST -H "Content-Type: application/json" -d '[
  {"name": "John Doe", "email": "john@example.com"},
  {"name": "Jane Smith", "email": "jane@example.com"},
  {"name": "Mike Johnson", "email": "mike@example.com"},
  {"name": "Emily Davis", "email": "emily@example.com"},
  {"name": "David Wilson", "email": "david@example.com"},
  {"name": "Sarah Thompson", "email": "sarah@example.com"},
  {"name": "Alex Miller", "email": "alex@example.com"},
  {"name": "Olivia Anderson", "email": "olivia@example.com"},
  {"name": "Daniel Martin", "email": "daniel@example.com"},
  {"name": "Sophia White", "email": "sophia@example.com"}
]' http://localhost:5000/users
```

- List the created users:

```
curl http://localhost:5000/users
```

- Get current time:

```
curl http://localhost:5001/current_time
```

- Run the ping against `example.com`:

```
curl -X POST -H "Content-Type: application/json" -d '{"host": "example.com"}'
http://localhost:5002/ping
```

#### J.5.4.3.5. Exploring the Database

Now that we called some API functions, data has been stored and we can check if the [citus\\_schemas](#) view reflects what we expect:

```
SELECT * FROM citus_schemas;
```

| schema_name  | colocation_id | schema_size | schema_owner |
|--------------|---------------|-------------|--------------|
| user_service | 1             | 112 kB      | user_service |
| time_service | 2             | 32 kB       | time_service |
| ping_service | 3             | 32 kB       | ping_service |

(3 rows)

At the time of schemas creation you do not instruct citus on which computer to create them. It is done automatically. Execute the following query to see where each schema resides:

```
SELECT nodename,nodeport, table_name, pg_size_pretty(sum(shard_size))
FROM citus_shards
GROUP BY nodename,nodeport, table_name;
```

| nodename  | nodeport | table_name                 | pg_size_pretty |
|-----------|----------|----------------------------|----------------|
| localhost | 9701     | time_service.query_details | 32 kB          |
| localhost | 9702     | user_service.users         | 112 kB         |
| localhost | 9702     | ping_service.ping_results  | 32 kB          |

We can see that the `time` service landed on node `localhost:9701`, while the `user` and `ping` services share space on the second worker `localhost:9702`. This is only an example, and the data sizes here can be ignored, but let us assume that we are annoyed by the uneven storage space utilization between the nodes. It makes more sense to have the two smaller `time` and `ping` services reside on one computer, while the large `user` service resides alone.

We can do this by instructing citus to rebalance the cluster by disk size:

```
SELECT citus_rebalance_start();

NOTICE:  Scheduled 1 moves as job 1
DETAIL:  Rebalance scheduled as background job
HINT:    To monitor progress, run: SELECT * FROM citus_rebalance_status();
citus_rebalance_start
```

1

(1 row)

When done, check how the new layout looks:

```
SELECT nodename,nodeport, table_name, pg_size_pretty(sum(shard_size))
FROM citus_shards
GROUP BY nodename,nodeport, table_name;
```

| nodename  | nodeport | table_name                 | pg_size_pretty |
|-----------|----------|----------------------------|----------------|
| localhost | 9701     | time_service.query_details | 32 kB          |
| localhost | 9701     | ping_service.ping_results  | 32 kB          |
| localhost | 9702     | user_service.users         | 112 kB         |

(3 rows)

We expect that the schemas have been moved and the cluster has become more balanced. This operation is transparent for the applications. Therefore, there is no need for a restart, and they will continue serving queries.

## J.5.5. Use Case Guides

### J.5.5.1. Multi-Tenant Applications

If you are building a Software-as-a-service (SaaS) application, you probably already have the notion of tenancy built into your data model. Typically, most information relates to tenants/customers/accounts and the database tables capture this natural relation.

For SaaS applications, each tenant's data can be stored together in a single database instance and kept isolated from and invisible to other tenants. This is efficient in three ways. First, application improvements apply to all clients. Second, sharing a database between tenants uses hardware efficiently. Last, it is much simpler to manage a single database for all tenants than a different database server for each tenant.

However, a single relational database instance has traditionally had trouble scaling to the volume of data needed for a large multi-tenant application. Developers were forced to relinquish the benefits of the relational model when data exceeded the capacity of a single database node.

The citus extension allows users to write multi-tenant applications as if they are connecting to a single Postgres Pro database, when in fact the database is a horizontally scalable cluster of computers. Client code requires minimal modifications and can continue to use full SQL capabilities.

This guide takes a sample multi-tenant application and describes how to model it for scalability with citus. Along the way typical challenges for multi-tenant applications are examined like isolating tenants from noisy neighbors, scaling hardware to accommodate more data, and storing data that differs across tenants. Postgres Pro and citus provide all the tools needed to handle these challenges, so let's get building.

#### **J.5.5.1.1. Let's Make an App: Ad Analytics**

We will build the back-end for an application that tracks online advertising performance and provides an analytics dashboard on top. It is a natural fit for a multi-tenant application because user requests for data concern one company (their own) at a time. Code for the full example application is [available](#) on GitHub.

Let's start by considering a simplified schema for this application. The application must keep track of multiple companies, each of which runs advertising campaigns. Campaigns have many ads, and each ad has associated records of its clicks and impressions.

Here is the example schema. We will make some minor changes later, which allow us to effectively distribute and isolate the data in a distributed environment.

```
CREATE TABLE companies (  
    id bigserial PRIMARY KEY,  
    name text NOT NULL,  
    image_url text,  
    created_at timestamp without time zone NOT NULL,  
    updated_at timestamp without time zone NOT NULL  
);  
  
CREATE TABLE campaigns (  
    id bigserial PRIMARY KEY,  
    company_id bigint REFERENCES companies (id),  
    name text NOT NULL,  
    cost_model text NOT NULL,  
    state text NOT NULL,  
    monthly_budget bigint,  
    blacklisted_site_urls text[],  
    created_at timestamp without time zone NOT NULL,  
    updated_at timestamp without time zone NOT NULL  
);  
  
CREATE TABLE ads (  
    id bigserial PRIMARY KEY,  
    campaign_id bigint REFERENCES campaigns (id),  
    name text NOT NULL,  
    image_url text,  
    target_url text,  
    impressions_count bigint DEFAULT 0,  
    clicks_count bigint DEFAULT 0,  
    created_at timestamp without time zone NOT NULL,  
    updated_at timestamp without time zone NOT NULL  
);
```

```

CREATE TABLE clicks (
  id bigserial PRIMARY KEY,
  ad_id bigint REFERENCES ads (id),
  clicked_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_click_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL
);

CREATE TABLE impressions (
  id bigserial PRIMARY KEY,
  ad_id bigint REFERENCES ads (id),
  seen_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_impression_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL
);

```

There are modifications we can make to the schema, which will give it a performance boost in a distributed environment like Citus. To see how, we must become familiar with how the extension distributes data and executes queries.

#### J.5.5.1.2. Scaling the Relational Data Model

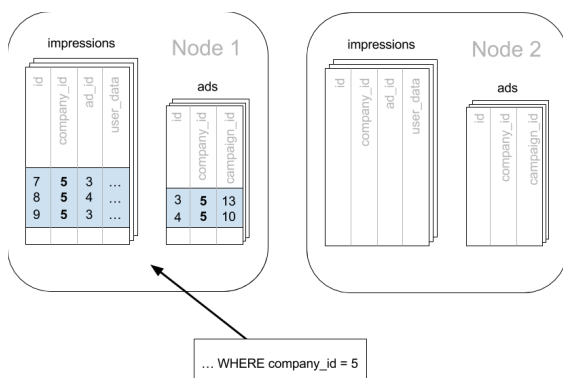

The relational data model is great for applications. It protects data integrity, allows flexible queries, and accommodates changing data. Traditionally the only problem was that relational databases were not considered capable of scaling to the workloads needed for big SaaS applications. Developers had to put up with NoSQL databases, or a collection of backend services, to reach that size.

With Citus you can keep your data model *and* make it scale. The extension appears to applications as a single Postgres Pro database, but it internally routes queries to an adjustable number of physical servers (nodes), which can process requests in parallel.

Multi-tenant applications have a nice property that we can take advantage of: queries usually always request information for one tenant at a time, not a mix of tenants. For instance, when a salesperson is searching prospect information in a CRM, the search results are specific to his employer; other businesses' leads and notes are not included.

Because application queries are restricted to a single tenant, such as a store or company, one approach for making multi-tenant application queries fast is to store *all* data for a given tenant on the same node. This minimizes network overhead between the nodes and allows Citus to support all your application's joins, key constraints and transactions efficiently. With this, you can scale across multiple nodes without having to totally re-write or re-architect your application. See the [figure](#) below to learn more.

**Figure J.1. Multi-Tenant Ad Routing Diagram**

This can be done in citus by making sure every table in our schema has a column to clearly mark which tenant owns which rows. In the ad analytics application the tenants are companies, so we must ensure all tables have a `company_id` column.

We can tell citus to use this column to read and write rows to the same node when the rows are marked for the same company. In citus terminology `company_id` is the *distribution column*, which you can learn more about in the [Choosing Distribution Column](#) section.

#### J.5.5.1.3. Preparing Tables and Ingesting Data

In the previous section we identified the correct distribution column for our multi-tenant application: `company_id`. Even in a single-computer database it can be useful to denormalize tables with the addition of `company_id`, whether it be for row-level security or for additional indexing. The extra benefit, as we saw, is that including the extra column helps for multi-machine scaling as well.

The schema we have created so far uses a separate `id` column as primary key for each table. citus requires that primary and foreign key constraints include the distribution column. This requirement makes enforcing these constraints much more efficient in a distributed environment as only a single node has to be checked to guarantee them.

In SQL, this requirement translates to making primary and foreign keys composite by including `company_id`. This is compatible with the multi-tenant case because what we really need there is to ensure uniqueness on a per-tenant basis.

Putting it all together, here are the changes that prepare the tables for distribution by `company_id`.

```
CREATE TABLE companies (  
  id bigserial PRIMARY KEY,  
  name text NOT NULL,  
  image_url text,  
  created_at timestamp without time zone NOT NULL,  
  updated_at timestamp without time zone NOT NULL  
);  
  
CREATE TABLE campaigns (  
  id bigserial,           -- was: PRIMARY KEY  
  company_id bigint REFERENCES companies (id),  
  name text NOT NULL,  
  cost_model text NOT NULL,  
  state text NOT NULL,  
  monthly_budget bigint,  
  blacklisted_site_urls text[],  
  created_at timestamp without time zone NOT NULL,  
  updated_at timestamp without time zone NOT NULL,  
  PRIMARY KEY (company_id, id) -- added  
);  
  
CREATE TABLE ads (  
  id bigserial,           -- was: PRIMARY KEY  
  company_id bigint,      -- added  
  campaign_id bigint,     -- was: REFERENCES campaigns (id)  
  name text NOT NULL,  
  image_url text,  
  target_url text,  
  impressions_count bigint DEFAULT 0,  
  clicks_count bigint DEFAULT 0,  
  created_at timestamp without time zone NOT NULL,  
  updated_at timestamp without time zone NOT NULL,  
  PRIMARY KEY (company_id, id),      -- added  
  FOREIGN KEY (company_id, campaign_id) -- added
```

```
REFERENCES campaigns (company_id, id)
);

CREATE TABLE clicks (
  id bigserial,          -- was: PRIMARY KEY
  company_id bigint,     -- added
  ad_id bigint,          -- was: REFERENCES ads (id),
  clicked_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_click_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL,
  PRIMARY KEY (company_id, id),      -- added
  FOREIGN KEY (company_id, ad_id)    -- added
    REFERENCES ads (company_id, id)
);

CREATE TABLE impressions (
  id bigserial,          -- was: PRIMARY KEY
  company_id bigint,     -- added
  ad_id bigint,          -- was: REFERENCES ads (id),
  seen_at timestamp without time zone NOT NULL,
  site_url text NOT NULL,
  cost_per_impression_usd numeric(20,10),
  user_ip inet NOT NULL,
  user_data jsonb NOT NULL,
  PRIMARY KEY (company_id, id),      -- added
  FOREIGN KEY (company_id, ad_id)    -- added
    REFERENCES ads (company_id, id)
);
```

You can learn more about migrating your own data model in the [Identify Distribution Strategy](#) section.

#### J.5.5.1.3.1. Practical Example

### Note

This guide is designed so you can follow along in your own citus database. This tutorial assumes that you already have the extension installed and running. If not, consult the [Installing citus on a Single Node](#) section to set up the extension locally.

1. At this point feel free to follow along in your own citus cluster by [downloading](#) and executing the SQL to create the schema. Once the schema is ready, we can tell citus to create shards on the workers. From the coordinator node run:

```
SELECT create_distributed_table('companies', 'id');
SELECT create_distributed_table('campaigns', 'company_id');
SELECT create_distributed_table('ads', 'company_id');
SELECT create_distributed_table('clicks', 'company_id');
SELECT create_distributed_table('impressions', 'company_id');
```

The [create\\_distributed\\_table](#) function informs citus that a table should be distributed among nodes and that future incoming queries to those tables should be planned for distributed execution. The function also creates shards for the table on worker nodes, which are low-level units of data storage citus uses to assign data to nodes.

2. The next step is loading sample data into the cluster from the command line:

```
# Download and ingest datasets from the shell
```

```
for dataset in companies campaigns ads clicks impressions geo_ips; do
  curl -O https://examples.citusdata.com/mt_ref_arch/${dataset}.csv
done
```

3. Being an extension of Postgres Pro, citus supports bulk loading with the `/copy` command. Use it to ingest the data you downloaded and make sure that you specify the correct file path if you downloaded the file to some other location. Back inside `psql` run this:

```
\copy companies from 'companies.csv' with csv
\copy campaigns from 'campaigns.csv' with csv
\copy ads from 'ads.csv' with csv
\copy clicks from 'clicks.csv' with csv
\copy impressions from 'impressions.csv' with csv
```

#### J.5.5.1.4. Integrating Applications

Once you have made the slight schema modification outlined earlier, your application can scale with very little work. You will just connect the app to citus and let the database take care of keeping the queries fast and the data safe.

Any application queries or update statements, which include a filter on `company_id`, will continue to work exactly as they are. As mentioned earlier, this kind of filter is common in multi-tenant apps. When using an Object-Relational Mapper (ORM) you can recognize these queries by methods such as `where` or `filter`.

ActiveRecord:

```
Impression.where(company_id: 5).count
```

Django:

```
Impression.objects.filter(company_id=5).count()
```

Basically when the resulting SQL executed in the database contains a `WHERE company_id = :value` clause on every table (including tables in `JOIN` queries), then citus will recognize that the query should be routed to a single node and execute it there as it is. This makes sure that all SQL functionality is available. The node is an ordinary Postgres Pro server after all.

Also, to make it even simpler, you can use our [activerecord-multi-tenant](#) library for Ruby on Rails, or [django-multitenant](#) for Django, which will automatically add these filters to all your queries, even the complicated ones. Check out our migration guides for [Ruby on Rails](#) and [Django](#).

This guide is framework-agnostic, so we will point out some citus features using SQL. Use your imagination for how these statements would be expressed in your language of choice.

Here is a simple query and update operating on a single tenant.

```
-- Campaigns with highest budget

SELECT name, cost_model, state, monthly_budget
FROM campaigns
WHERE company_id = 5
ORDER BY monthly_budget DESC
LIMIT 10;

-- Double the budgets!

UPDATE campaigns
SET monthly_budget = monthly_budget*2
WHERE company_id = 5;
```

A common pain point for users scaling applications with NoSQL databases is the lack of transactions and joins. However, transactions work as you would expect them to in Citus:

```
-- Transactionally reallocate campaign budget money

BEGIN;

UPDATE campaigns
  SET monthly_budget = monthly_budget + 1000
  WHERE company_id = 5
  AND id = 40;

UPDATE campaigns
  SET monthly_budget = monthly_budget - 1000
  WHERE company_id = 5
  AND id = 41;

COMMIT;
```

As a final demo of SQL support, we have a query that includes aggregates and window functions and it works the same in Citus as it does in Postgres Pro. The query ranks the ads in each campaign by the count of their impressions.

```
SELECT a.campaign_id,
       RANK() OVER (
         PARTITION BY a.campaign_id
         ORDER BY a.campaign_id, count(*) desc
       ), count(*) as n_impressions, a.id
FROM ads as a
JOIN impressions as i
  ON i.company_id = a.company_id
  AND i.ad_id = a.id
WHERE a.company_id = 5
GROUP BY a.campaign_id, a.id
ORDER BY a.campaign_id, n_impressions desc;
```

In short, when queries are scoped to a tenant then the `INSERT`, `UPDATE`, `DELETE`, complex SQL commands, and transactions all work as expected.

#### J.5.5.1.5. Sharing Data Between Tenants

Up until now all tables have been distributed by `company_id`, but sometimes there is data that can be shared by all tenants and does not “belong” to any tenant in particular. For instance, all companies using this example ad platform might want to get geographical information for their audience based on IP addresses. In a single computer database this could be accomplished by a lookup table for geo-ip, like the following. (A real table would probably use PostGIS, but bear with the simplified example.)

```
CREATE TABLE geo_ips (
  addr inet NOT NULL PRIMARY KEY,
  latlon point NOT NULL
  CHECK (-90 <= latlon[0] AND latlon[0] <= 90 AND
        -180 <= latlon[1] AND latlon[1] <= 180)
);
CREATE INDEX ON geo_ips USING gist (addr inet_ops);
```

To use this table efficiently in a distributed setup, we need to find a way to co-locate the `geo_ips` table with clicks for not just one but every company. That way, no network traffic need be incurred at query time. This can be done in Citus by designating `geo_ips` as a [reference table](#).

```
-- Make synchronized copies of geo_ips on all workers
```

```
SELECT create_reference_table('geo_ips');
```

Reference tables are replicated across all worker nodes, and citus automatically keeps them in sync during modifications. Notice that we call the [create\\_reference\\_table](#) function rather than the [create\\_distributed\\_table](#) function.

Now that `geo_ips` is established as a reference table, load it with example data:

```
\copy geo_ips from 'geo_ips.csv' with csv
```

Now joining clicks with this table can execute efficiently. We can ask, for example, the locations of everyone who clicked on ad 290.

```
SELECT c.id, clicked_at, latlon
FROM geo_ips, clicks c
WHERE addr >> c.user_ip
AND c.company_id = 5
AND c.ad_id = 290;
```

#### J.5.5.1.6. Online Changes to the Schema

Another challenge with multi-tenant systems is keeping the schemas for all the tenants in sync. Any schema change needs to be consistently reflected across all the tenants. In citus, you can simply use standard Postgres Pro DDL commands to change the schema of your tables, and the extension will propagate them from the coordinator node to the workers using a two-phase commit protocol.

For example, the advertisements in this application could use a text caption. We can add a column to the table by issuing the standard SQL on the coordinator:

```
ALTER TABLE ads
ADD COLUMN caption text;
```

This updates all the workers as well. Once this command finishes, the citus cluster will accept queries that read or write data in the new `caption` column.

For a fuller explanation of how DDL commands propagate through the cluster, see the [Modifying Tables](#) section.

#### J.5.5.1.7. When Data Differs Across Tenants

Given that all tenants share a common schema and hardware infrastructure, how can we accommodate tenants, which want to store information not needed by others? For example, one of the tenant applications using our advertising database may want to store tracking cookie information with clicks, whereas another tenant may care about browser agents. Traditionally databases using a shared schema approach for multi-tenancy have resorted to creating a fixed number of pre-allocated “custom” columns, or having external “extension tables”. However, Postgres Pro provides a much easier way with its unstructured column types, notably [JSONB](#).

Notice that our schema already has a JSONB field in `clicks` called `user_data`. Each tenant can use it for flexible storage.

Suppose company five includes information in the field to track whether the user is on a mobile device. The company can query to find who clicks more, mobile or traditional visitors:

```
SELECT
  user_data->>'is_mobile' AS is_mobile,
  count(*) AS count
FROM clicks
WHERE company_id = 5
GROUP BY user_data->>'is_mobile'
```

```
ORDER BY count DESC;
```

The database administrator can even create a [partial index](#) to improve speed for an individual tenant's query patterns. Here is one to improve filters for clicks of the company with `company_id = 5` from users on mobile devices:

```
CREATE INDEX click_user_data_is_mobile
ON clicks ((user_data->>'is_mobile'))
WHERE company_id = 5;
```

Additionally, Postgres Pro supports [GIN indices](#) on JSONB. Creating a GIN index on a JSONB column will create an index on every key and value within that JSON document. This speeds up a number of [JSONB operators](#) such as `?`, `?|`, and `?&`.

```
CREATE INDEX click_user_data
ON clicks USING gin (user_data);

-- this speeds up queries like, "which clicks have
-- the is_mobile key present in user_data?"

SELECT id
FROM clicks
WHERE user_data ? 'is_mobile'
AND company_id = 5;
```

#### J.5.5.1.8. Scaling Hardware Resources

Multi-tenant databases should be designed for future scale as business grows or tenants want to store more data. Citus can scale out easily by adding new computers without having to make any changes or take application downtime.

Being able to rebalance data in the Citus cluster allows you to grow your data size or number of customers and improve performance on demand. Adding new computers allows you to keep data in memory even when it is much larger than what a single computer can store.

Also, if data increases for only a few large tenants, then you can isolate those particular tenants to separate nodes for better performance.

To scale out your Citus cluster, first add a new worker node to it with the [citus\\_add\\_node](#) function.

Once you add the node it is available in the system. However, at this point no tenants are stored on it and Citus will not yet run any queries there. To move your existing data, you can ask Citus to rebalance the data. This operation moves bundles of rows called shards between the currently active nodes to attempt to equalize the amount of data on each node.

```
SELECT citus_rebalance_start();
```

Applications do not need to undergo downtime during shard rebalancing. Read requests continue seamlessly, and writes are locked only when they affect shards, which are currently in flight. In Citus writes to shards are blocked during rebalancing but reads are unaffected.

#### J.5.5.1.9. Dealing with Big Tenants

The previous section describes a general-purpose way to scale a cluster as the number of tenants increases. However, users often have two questions. The first is what will happen to their largest tenant if it grows too big. The second is what are the performance implications of hosting a large tenant together with small ones on a single worker node.

Regarding the first question, investigating data from large SaaS sites reveals that as the number of tenants increases, the size of tenant data typically tends to follow a [Zipfian distribution](#). See the [figure](#) below to learn more.

**Figure J.2. Zipfian Distribution**

For instance, in a database of 100 tenants, the largest is predicted to account for about 20% of the data. In a more realistic example for a large SaaS company, if there are 10,000 tenants, the largest will account for around 2% of the data. Even at 10TB of data, the largest tenant will require 200GB, which can pretty easily fit on a single node.

Another question is regarding performance when large and small tenants are on the same node. Standard shard rebalancing will improve overall performance but it may or may not improve the mixing of large and small tenants. The rebalancer simply distributes shards to equalize storage usage on nodes, without examining which tenants are allocated on each shard.

To improve resource allocation and make guarantees of tenant QoS it is worthwhile to move large tenants to dedicated nodes. The citus extension provides the tools to do this.

In our case, let's imagine that the company with `company_id=5` is very large. We can isolate the data for this tenant in two steps. We will present the commands here, and you can consult the [Tenant Isolation](#) section to learn more about them.

First isolate the tenant's data to a dedicated shard suitable to move. The `CASCADE` option also applies this change to the rest of our tables distributed by `company_id`.

```
SELECT isolate_tenant_to_new_shard(
    'companies', 5, 'CASCADE'
);
```

The output is the shard ID dedicated to hold `company_id=5`:

| isolate_tenant_to_new_shard |
|-----------------------------|
| 102240                      |

Next we move the data across the network to a new dedicated node. Create a new node as described in the previous section. Take note of its hostname.

```
-- Find the node currently holding the new shard

SELECT nodename, nodeport
FROM pg_dist_placement AS placement,
     pg_dist_node AS node
WHERE placement.groupid = node.groupid
      AND node.noderole = 'primary'
      AND shardid = 102240;

-- Move the shard to your choice of worker (it will also move the
-- other shards created with the CASCADE option)
```

```
-- Note that you should set wal_level for all nodes to be >= logical
-- to use citus_move_shard_placement
-- You also need to restart your cluster after setting wal_level in
-- postgresql.conf files
```

```
SELECT citus_move_shard_placement(
    102240,
    'source_host', source_port,
    'dest_host', dest_port);
```

You can confirm the shard movement by querying the [pg\\_dist\\_placement](#) table again.

#### J.5.5.1.10. Where to Go From Here

With this, you now know how to use citus to power your multi-tenant application for scalability. If you have an existing schema and want to migrate it for citus, see the [Migrating an Existing App](#) section.

To adjust a front-end application, specifically Ruby on Rails or Django, read [Ruby on Rails](#) or [Django](#) migration guides.

### J.5.5.2. Real-Time Dashboards

citus provides real-time queries over large datasets. One workload we commonly see at citus involves powering real-time dashboards of event data.

For example, you could be a cloud services provider helping other businesses monitor their HTTP traffic. Every time one of your clients receives an HTTP request your service receives a log record. You want to ingest all those records and create an HTTP analytics dashboard that gives your clients insights such as the number HTTP errors their sites served. It is important that this data shows up with as little latency as possible so your clients can fix problems with their sites. It is also important for the dashboard to show graphs of historical trends.

Alternatively, maybe you are building an advertising network and want to show clients clickthrough rates on their campaigns. In this example latency is also critical, raw data volume is also high, and both historical and live data are important.

In this section we will demonstrate how to build part of the first example, but this architecture would work equally well for the second and many other use cases.

#### J.5.5.2.1. Data Model

The data we are dealing with is an immutable stream of log data. We will insert directly into citus but it is also common for this data to first be routed through something like Kafka. Doing so has the usual advantages, and makes it easier to pre-aggregate the data once data volumes become unmanageably high.

We will use a simple schema for ingesting HTTP event data. This schema serves as an example to demonstrate the overall architecture; a real system might use additional columns.

```
-- This is run on the coordinator

CREATE TABLE http_request (
    site_id INT,
    ingest_time TIMESTAMPTZ DEFAULT now(),

    url TEXT,
    request_country TEXT,
    ip_address TEXT,

    status_code INT,
    response_time_msec INT
```

```
);

SELECT create_distributed_table('http_request', 'site_id');
```

When we call the [create\\_distributed\\_table](#) function we ask citus to hash-distribute `http_request` using the `site_id` column. That means all the data for a particular site will live in the same shard.

The user defined functions use the default configuration values for shard count. We recommend [using 2-4x as many shards](#) as CPU cores in your cluster. Using this many shards lets you rebalance data across your cluster after adding new worker nodes.

With this, the system is ready to accept data and serve queries. Keep the following loop running in a `psql` console in the background while you continue with the other commands in this article. It generates fake data every second or two.

```
DO $$
BEGIN LOOP
  INSERT INTO http_request (
    site_id, ingest_time, url, request_country,
    ip_address, status_code, response_time_msec
  ) VALUES (
    trunc(random()*32), clock_timestamp(),
    concat('http://example.com/', md5(random()::text)),
    ('{China,India,USA,Indonesia}'::text[])[ceil(random()*4)],
    concat(
      trunc(random()*250 + 2), '.',
      trunc(random()*250 + 2), '.',
      trunc(random()*250 + 2), '.',
      trunc(random()*250 + 2)
    )::inet,
    ('{200,404}'::int[])[ceil(random()*2)],
    5+trunc(random()*150)
  );
  COMMIT;
  PERFORM pg_sleep(random() * 0.25);
END LOOP;
END $$;
```

Once you are ingesting data, you can run dashboard queries such as:

```
SELECT
  site_id,
  date_trunc('minute', ingest_time) as minute,
  COUNT(1) AS request_count,
  SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as success_count,
  SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count,
  SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
FROM http_request
WHERE date_trunc('minute', ingest_time) > now() - '5 minutes'::interval
GROUP BY site_id, minute
ORDER BY minute ASC;
```

The setup described above works but has two drawbacks:

- Your HTTP analytics dashboard must go over each row every time it needs to generate a graph. For example, if your clients are interested in trends over the past year, your queries will aggregate every row for the past year from scratch.
- Your storage costs will grow proportionally with the ingest rate and the length of the queryable history. In practice, you may want to keep raw events for a shorter period of time (one month) and look at historical graphs over a longer time period (years).

### J.5.5.2.2. Rollups

You can overcome both drawbacks by rolling up the raw data into a pre-aggregated form. Here, we will aggregate the raw data into a table, which stores summaries of 1-minute intervals. In a production system, you would probably also want something like 1-hour and 1-day intervals, these each correspond to zoom-levels in the dashboard. When the user wants request times for the last month the dashboard can simply read and chart the values for each of the last 30 days.

```
CREATE TABLE http_request_1min (
  site_id INT,
  ingest_time TIMESTAMPTZ, -- which minute this row represents

  error_count INT,
  success_count INT,
  request_count INT,
  average_response_time_msec INT,
  CHECK (request_count = error_count + success_count),
  CHECK (ingest_time = date_trunc('minute', ingest_time))
);

SELECT create_distributed_table('http_request_1min', 'site_id');

CREATE INDEX http_request_1min_idx ON http_request_1min (site_id, ingest_time);
```

This looks a lot like the previous code block. Most importantly: It also shards on `site_id` and uses the same default configuration for shard count. Because all three of those match, there is a 1-to-1 correspondence between `http_request` shards and `http_request_1min` shards, and citus will place matching shards on the same worker. This is called [co-location](#); it makes queries such as joins faster and our rollups possible. See the [figure](#) below to learn more.

**Figure J.3. Collocation Diagram**

In order to populate `http_request_1min` we are going to periodically run `INSERT INTO SELECT`. This is possible because the tables are co-located. The following function wraps the rollup query up for convenience.

```
-- Single-row table to store when we rolled up last
CREATE TABLE latest_rollup (
  minute timestamptz PRIMARY KEY,

  -- "minute" should be no more precise than a minute
  CHECK (minute = date_trunc('minute', minute))
);

-- Initialize to a time long ago
INSERT INTO latest_rollup VALUES ('10-10-1901');

-- Function to do the rollup
CREATE OR REPLACE FUNCTION rollup_http_request() RETURNS void AS $$
DECLARE
  curr_rollup_time timestamptz := date_trunc('minute', now() - interval '1 minute');
```

```
last_rollup_time timestamptz := minute from latest_rollup;
BEGIN
  INSERT INTO http_request_1min (
    site_id, ingest_time, request_count,
    success_count, error_count, average_response_time_msec
  ) SELECT
    site_id,
    date_trunc('minute', ingest_time),
    COUNT(1) as request_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as
success_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count,
    SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
  FROM http_request
  -- Roll up only data new since last_rollup_time
  WHERE date_trunc('minute', ingest_time) <@
    tstzrange(last_rollup_time, curr_rollup_time, '[]')
  GROUP BY 1, 2;

  -- Update the value in latest_rollup so that next time we run the
  -- rollup it will operate on data newer than curr_rollup_time
  UPDATE latest_rollup SET minute = curr_rollup_time;
END;
$$ LANGUAGE plpgsql;
```

### Note

The above function should be called every minute. You could do this by adding a `crontab` entry on the coordinator node:

```
* * * * * psql -c 'SELECT rollup_http_request();'
```

Alternatively, an extension such as [pg\\_cron](#) allows you to schedule recurring queries directly from the database.

The dashboard query from earlier is now a lot nicer:

```
SELECT site_id, ingest_time as minute, request_count,
       success_count, error_count, average_response_time_msec
  FROM http_request_1min
 WHERE ingest_time > date_trunc('minute', now()) - '5 minutes'::interval;
```

#### J.5.5.2.3. Expiring Old Data

The rollups make queries faster, but we still need to expire old data to avoid unbounded storage costs. Simply decide how long you would like to keep data for each granularity and use standard queries to delete expired data. In the following example, we decided to keep raw data for one day, and per-minute aggregations for one month:

```
DELETE FROM http_request WHERE ingest_time < now() - interval '1 day';
DELETE FROM http_request_1min WHERE ingest_time < now() - interval '1 month';
```

In production you could wrap these queries in a function and call it every minute in a `cron` job.

Data expiration can go even faster by using table range partitioning on top of citus hash distribution. See the [Timeseries Data](#) section for a detailed example.

Those are the basics. We provided an architecture that ingests HTTP events and then rolls up these events into their pre-aggregated form. This way you can both store raw events and also power your analytical dashboards with subsecond queries.

The next sections extend upon the basic architecture and show you how to resolve questions, which often appear.

#### J.5.5.2.4. Approximate Distinct Counts

A common question in HTTP analytics deals with [approximate distinct counts](#): How many unique visitors visited your site over the last month? Answering this question *exactly* requires storing the list of all previously seen visitors in the rollup tables, a prohibitively large amount of data. However, an approximate answer is much more manageable.

A datatype called HyperLogLog, or `hll`, can answer the query approximately; it takes a surprisingly small amount of space to tell you approximately how many unique elements are in a set. Its accuracy can be adjusted. We will use ones which, using only 1,280 bytes, will be able to count up to tens of billions of unique visitors with at most 2.2% error.

An equivalent problem appears if you want to run a global query, such as the number of unique IP addresses, which visited any of your client's sites over the last month. Without `hll` this query involves shipping lists of IP addresses from the workers to the coordinator for it to deduplicate. That is both a lot of network traffic and a lot of computation. By using `hll` you can greatly improve query speed.

You can install the `hll` extension, whose instructions are available in [the GitHub repository](#), and enable it as follows:

```
CREATE EXTENSION hll;
```

Now we are ready to track IP addresses in our rollup with `hll`. First add a column to the rollup table.

```
ALTER TABLE http_request_1min ADD COLUMN distinct_ip_addresses hll;
```

Next use our custom aggregation to populate the column. Just add it to the query in our rollup function:

```
@@ -1,10 +1,12 @@
  INSERT INTO http_request_1min (
    site_id, ingest_time, request_count,
    success_count, error_count, average_response_time_msec
+   , distinct_ip_addresses
  ) SELECT
    site_id,
    date_trunc('minute', ingest_time),
    COUNT(1) as request_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as
success_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count,
    SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
+   , hll_add_agg(hll_hash_text(ip_address)) AS distinct_ip_addresses
  FROM http_request
```

Dashboard queries are a little more complicated, you have to read out the distinct number of IP addresses by calling the `hll_cardinality` function:

```
SELECT site_id, ingest_time as minute, request_count,
       success_count, error_count, average_response_time_msec,
       hll_cardinality(distinct_ip_addresses) AS distinct_ip_address_count
  FROM http_request_1min
 WHERE ingest_time > date_trunc('minute', now()) - interval '5 minutes';
```

`hll` is not just faster, it lets you do things you could not previously. Say we did our rollups, but instead of using `hll` we saved the exact unique counts. This works fine, but you cannot answer queries such as “how many distinct sessions were there during this one-week period in the past we've thrown away the raw data for?”.

With `hll`, this is easy. You can compute distinct IP counts over a time period with the following query:

```
SELECT hll_cardinality(hll_union_agg(distinct_ip_addresses))
FROM http_request_1min
WHERE ingest_time > date_trunc('minute', now()) - '5 minutes'::interval;
```

You can find more information about the hll extension in the [project's GitHub repository](#).

#### J.5.5.2.5. Unstructured Data with JSONB

The citus extension works well with Postgres Pro built-in support for unstructured data types. To demonstrate this, let's keep track of the number of visitors, which came from each country. Using a semi-structure data type saves you from needing to add a column for every individual country and ending up with rows that have hundreds of sparsely filled columns. It is recommended to use the JSONB format, here we will demonstrate how to incorporate JSONB columns into your data model.

First, add the new column to our rollup table:

```
ALTER TABLE http_request_1min ADD COLUMN country_counters JSONB;
```

Next, include it in the rollups by modifying the rollup function:

```
@@ -1,14 +1,19 @@
INSERT INTO http_request_1min (
    site_id, ingest_time, request_count,
    success_count, error_count, average_response_time_msec
+   , country_counters
) SELECT
    site_id,
    date_trunc('minute', ingest_time),
    COUNT(1) as request_count,
    SUM(CASE WHEN (status_code between 200 and 299) THEN 1 ELSE 0 END) as success_count
    SUM(CASE WHEN (status_code between 200 and 299) THEN 0 ELSE 1 END) as error_count
    SUM(response_time_msec) / COUNT(1) AS average_response_time_msec
- FROM http_request
+   , jsonb_object_agg(request_country, country_count) AS country_counters
+ FROM (
+   SELECT *,
+       count(1) OVER (
+         PARTITION BY site_id, date_trunc('minute', ingest_time), request_country
+       ) AS country_count
+   FROM http_request
+ ) h
```

Now, if you want to get the number of requests that came from America in your dashboard, you can modify the dashboard query to look like this:

```
SELECT
    request_count, success_count, error_count, average_response_time_msec,
    COALESCE(country_counters->>'USA', '0')::int AS american_visitors
FROM http_request_1min
WHERE ingest_time > date_trunc('minute', now()) - '5 minutes'::interval;
```

#### J.5.5.3. Timeseries Data

In a timeseries workload, applications (such as some [real-time apps](#)) query recent information, while archiving old information.

To deal with this workload, a single-node Postgres Pro database would typically use [table partitioning](#) to break a big table of time-ordered data into multiple inherited tables with each containing different time ranges.

Storing data in multiple physical tables speeds up data expiration. In a single big table, deleting rows incurs the cost of scanning to find which to delete, and then [vacuuming](#) the emptied space. On the other

hand, dropping a partition is a fast operation independent of data size. It is the equivalent of simply removing files on disk that contain the data. See the [figure](#) below to learn more.

**Figure J.4. Delete vs. Drop Diagram**

Partitioning a table also makes indices smaller and faster within each date range. Queries operating on recent data are likely to operate on “hot” indices that fit in memory. This speeds up reads. See the [figure](#) below to learn more.

**Figure J.5. SELECT Across Multiple Indexes**

Also inserts have smaller indices to update, so they go faster too. See the [figure](#) below to learn more.

**Figure J.6. INSERT Across Multiple Indexes**

Time-based partitioning makes most sense when:

1. Most queries access a very small subset of the most recent data.
2. Older data is periodically expired (deleted/dropped).

Keep in mind that, in the wrong situation, reading all these partitions can hurt overhead more than it helps. However, in the right situations it is quite helpful. For example, when keeping a year of time series data and regularly querying only the most recent week.

#### J.5.5.3.1. Scaling Timeseries Data on citus

We can mix the single-node table partitioning techniques with citus distributed sharding to make a scalable time-series database. It is the best of both worlds. It is especially elegant atop Postgres Pro declarative table partitioning. See the [figure](#) below to learn more.

**Figure J.7. Timeseries Sharding and Partitioning**

For example, let's distribute *and* partition a table holding the historical [GitHub events data](#).

Each record in this GitHub data set represents an event created in GitHub, along with key information regarding the event such as event type, creation date, and the user who created the event.

The first step is to create and partition the table by time as we would in a single-node Postgres Pro database:

```
-- Declaratively partitioned table
CREATE TABLE github_events (
    event_id bigint,
    event_type text,
    event_public boolean,
    repo_id bigint,
    payload jsonb,
    repo jsonb,
    actor jsonb,
    org jsonb,
    created_at timestamp
) PARTITION BY RANGE (created_at);
```

Notice the `PARTITION BY RANGE (created_at)`. This tells Postgres Pro that the table will be partitioned by the `created_at` column in ordered ranges. We have not yet created any partitions for specific ranges, though.

Before creating specific partitions, let's distribute the table in citus. We will shard by `repo_id`, meaning the events will be clustered into shards per repository.

```
SELECT create_distributed_table('github_events', 'repo_id');
```

At this point citus has created shards for this table across worker nodes. Internally each shard is a table with the name `github_events_N` for each shard identifier `N`. Also, citus propagated the partitioning information, and each of these shards has `Partition key: RANGE (created_at)` declared.

A partitioned table cannot directly contain data, it is more like a view across its partitions. Thus the shards are not yet ready to hold data. We need to create partitions and specify their time ranges, after which we can insert data that match the ranges.

#### J.5.5.3.2. Automating Partition Creation

citus provides helper functions for partition management. We can create a batch of monthly partitions using the [create\\_time\\_partitions](#) function:

```
SELECT create_time_partitions(
    table_name      := 'github_events',
    partition_interval := '1 month',
    end_at          := now() + '12 months'
);
```

citus also includes the [time\\_partitions](#) view for an easy way to investigate the partitions it has created.

```
SELECT partition
FROM time_partitions
WHERE parent_table = 'github_events'::regclass;
```

| partition              |
|------------------------|
| github_events_p2021_10 |
| github_events_p2021_11 |
| github_events_p2021_12 |
| github_events_p2022_01 |
| github_events_p2022_02 |
| github_events_p2022_03 |
| github_events_p2022_04 |
| github_events_p2022_05 |
| github_events_p2022_06 |

```
| github_events_p2022_07 |  
| github_events_p2022_08 |  
| github_events_p2022_09 |  
| github_events_p2022_10 |
```

As time progresses, you will need to do some maintenance to create new partitions and drop old ones. It is best to set up a periodic job to run the maintenance functions with an extension like [pg\\_cron](#):

```
-- Set two monthly cron jobs:  
  
-- 1. Ensure we have partitions for the next 12 months  
  
SELECT cron.schedule('create-partitions', '0 0 1 * *', $$  
    SELECT create_time_partitions(  
        table_name           := 'github_events',  
        partition_interval := '1 month',  
        end_at               := now() + '12 months'  
    )  
$$);  
  
-- 2. (Optional) Ensure we never have more than one year of data  
  
SELECT cron.schedule('drop-partitions', '0 0 1 * *', $$  
    CALL drop_old_time_partitions(  
        'github_events',  
        now() - interval '12 months' /* older_than */  
    )  
$$);
```

### Note

Be aware that native partitioning in Postgres Pro is still quite new and has a few quirks. Maintenance operations on partitioned tables will acquire aggressive locks that can briefly stall queries.

#### J.5.5.3.3. Archiving with Columnar Storage

Some applications have data that logically divides into a small updatable part and a larger part that is “frozen”. Examples include logs, clickstreams, or sales records. In this case we can combine partitioning with [columnar table storage](#) to compress historical partitions on disk. Citus columnar tables are currently append-only, meaning they do not support updates or deletes, but we can use them for the immutable historical partitions.

A partitioned table may be made up of any combination of row and columnar partitions. When using range partitioning on a timestamp key, we can make the newest partition a row table, and periodically roll the newest partition into another historical columnar partition.

Let's see an example, using GitHub events again. We will create a new table called `github_columnar_events` for disambiguation from the earlier example. To focus entirely on the columnar storage aspect, we will not distribute this table.

Next, download sample data:

```
wget http://examples.citusdata.com/github_archive/github_events-2015-01-01-  
{0..5}.csv.gz  
gzip -c -d github_events-2015-01-01-*.gz >> github_events.csv  
  
-- Our new table, same structure as the example in  
-- the previous section
```

```
CREATE TABLE github_columnar_events ( LIKE github_events )
PARTITION BY RANGE (created_at);

-- Create partitions to hold two hours of data each

SELECT create_time_partitions(
    table_name      := 'github_columnar_events',
    partition_interval := '2 hours',
    start_from      := '2015-01-01 00:00:00',
    end_at          := '2015-01-01 08:00:00'
);

-- Fill with sample data
-- (note that this data requires the database to have UTF8 encoding)

\COPY github_columnar_events FROM 'github_events.csv' WITH (format CSV)

-- List the partitions, and confirm they are
-- using row-based storage (heap access method)

SELECT partition, access_method
FROM time_partitions
WHERE parent_table = 'github_columnar_events'::regclass;
```

| partition                               | access_method |
|-----------------------------------------|---------------|
| github_columnar_events_p2015_01_01_0000 | heap          |
| github_columnar_events_p2015_01_01_0200 | heap          |
| github_columnar_events_p2015_01_01_0400 | heap          |
| github_columnar_events_p2015_01_01_0600 | heap          |

```
-- Convert older partitions to use columnar storage

CALL alter_old_partitions_set_access_method(
    'github_columnar_events',
    '2015-01-01 06:00:00' /* older_than */,
    'columnar'
);

-- The old partitions are now columnar, while the
-- latest uses row storage and can be updated

SELECT partition, access_method
FROM time_partitions
WHERE parent_table = 'github_columnar_events'::regclass;
```

| partition                               | access_method |
|-----------------------------------------|---------------|
| github_columnar_events_p2015_01_01_0000 | columnar      |
| github_columnar_events_p2015_01_01_0200 | columnar      |
| github_columnar_events_p2015_01_01_0400 | columnar      |
| github_columnar_events_p2015_01_01_0600 | heap          |

To see the compression ratio for a columnar table, use `VACUUM VERBOSE`. The compression ratio for our three columnar partitions is pretty good:

```
VACUUM VERBOSE github_columnar_events;

INFO:  statistics for "github_columnar_events_p2015_01_01_0000":
storage id: 100000000003
total file size: 4481024, total data size: 4444425
compression rate: 8.31x
total row count: 15129, stripe count: 1, average rows per stripe: 15129
chunk count: 18, containing data for dropped columns: 0, zstd compressed: 18

INFO:  statistics for "github_columnar_events_p2015_01_01_0200":
storage id: 100000000004
total file size: 3579904, total data size: 3548221
compression rate: 8.26x
total row count: 12714, stripe count: 1, average rows per stripe: 12714
chunk count: 18, containing data for dropped columns: 0, zstd compressed: 18

INFO:  statistics for "github_columnar_events_p2015_01_01_0400":
storage id: 100000000005
total file size: 2949120, total data size: 2917407
compression rate: 8.51x
total row count: 11756, stripe count: 1, average rows per stripe: 11756
chunk count: 18, containing data for dropped columns: 0, zstd compressed: 18
```

One power of the partitioned table `github_columnar_events` is that it can be queried in its entirety like a normal table.

```
SELECT COUNT(DISTINCT repo_id)
FROM github_columnar_events;
```

| count |
|-------|
| 16001 |

Entries can be updated or deleted, as long as there is a `WHERE` clause on the partition key, which filters entirely into row table partitions.

#### Archiving a Row Partition to Columnar Storage

When a row partition has filled its range, you can archive it to compressed columnar storage. We can automate this with `pg_cron` like so:

```
-- A monthly cron job

SELECT cron.schedule('compress-partitions', '0 0 1 * *', $$
CALL alter_old_partitions_set_access_method(
    'github_columnar_events',
    now() - interval '6 months' /* older_than */,
    'columnar'
);
$$);
```

For more information, see the [Columnar Storage](#) section.

## J.5.6. Architecture Concepts

### J.5.6.1. Nodes

`citus` is a Postgres Pro [extension](#) that allows commodity database servers (called *nodes*) to coordinate with one another in a “shared-nothing” architecture. The nodes form a *cluster* that allows Postgres Pro to hold more data and use more CPU cores than would be possible on a single computer. This architecture also allows the database to scale by simply adding more nodes to the cluster.

Every cluster has one special node called the *coordinator* (the others are known as workers). Applications send their queries to the coordinator node, which relays it to the relevant workers and accumulates the results.

For each query, the coordinator either *routes* it to a single worker node, or *parallelizes* it across several depending on whether the required data lives on a single node or multiple. The coordinator knows how to do this by consulting its metadata tables. These tables specific to citus track the DNS names and health of worker nodes, and the distribution of data across nodes. For more information, see the [citus Tables and Views](#) section.

### J.5.6.2. Sharding Models

Sharding is a technique used in database systems and distributed computing to horizontally partition data across multiple servers or nodes. It involves breaking up a large database or dataset into smaller, more manageable parts called [shards](#). Each shard contains a subset of the data, and together they form the complete dataset.

citus offers two types of data sharding: row-based and schema-based. Each option comes with its own [sharding tradeoffs](#) allowing you to choose the approach that best aligns with requirements of your application.

#### J.5.6.2.1. Row-Based Sharding

The traditional way in which citus shards tables is the single database, shared schema model also known as row-based sharding, tenants co-exist as rows within the same table. The tenant is determined by defining the [distribution column](#), which allows splitting up a table horizontally.

This is the most hardware efficient way of sharding. Tenants are densely packed and distributed among the nodes in the cluster. This approach, however, requires making sure that all tables in the schema have the distribution column and that all queries in the application filter by it. Row-based sharding shines in IoT workloads and for achieving the best margin out of hardware use.

Benefits:

- Best performance
- Best tenant density per node

Drawbacks:

- Requires schema modifications
- Requires application query modifications
- All tenants must share the same schema

#### J.5.6.2.2. Schema-Based Sharding

Schema-based sharding is the shared database, separate schema model, the schema becomes the logical shard within the database. Multi-tenant apps can use a schema per tenant to easily shard along the tenant dimension. Query changes are not required and the application usually only needs a small modification to set the proper `search_path` when switching tenants. Schema-based sharding is an ideal solution for microservices, and for ISVs deploying applications that cannot undergo the changes required to onboard row-based sharding.

Benefits:

- Tenants can have heterogeneous schemas
- No schema modifications required
- No application query modifications required
- [Schema-based sharding SQL compatibility](#) is better compared to the row-based sharding

Drawbacks:

- Fewer tenants per node compared to row-based sharding

### J.5.6.2.3. Sharding Tradeoffs

|                                           | Schema-Based Sharding                              | Row-Based Sharding                                                                                                                                       |
|-------------------------------------------|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multi-tenancy model                       | Separate schema per tenant                         | Shared tables with tenant ID columns                                                                                                                     |
| citus version                             | 12.0+                                              | All versions                                                                                                                                             |
| Additional steps compared to Postgres Pro | None, only a config change                         | Use the <a href="#">create_distributed_table</a> function on each table to distribute and co-locate tables by <code>tenant_id</code>                     |
| Number of tenants                         | 1-10k                                              | 1-1M+                                                                                                                                                    |
| Data modelling requirement                | No foreign keys across distributed schemas         | Need to include the <code>tenant_id</code> column (a distribution column, also known as a sharding key) in each table, and in primary keys, foreign keys |
| SQL requirement for single node queries   | Use a single distributed schema per query          | Joins and <code>WHERE</code> clauses should include <code>tenant_id</code> column                                                                        |
| Parallel cross-tenant queries             | No                                                 | Yes                                                                                                                                                      |
| Custom table definitions per tenant       | Yes                                                | No                                                                                                                                                       |
| Access control                            | Schema permissions                                 | Schema permissions                                                                                                                                       |
| Data sharing across tenants               | Yes, using reference tables (in a separate schema) | Yes, using reference tables                                                                                                                              |
| Tenant to shard isolation                 | Every tenant has its own shard group by definition | Can give specific tenant IDs their own shard group via the <a href="#">isolate_tenant_to_new_shard</a> function.                                         |

## J.5.6.3. Distributed Data

### J.5.6.3.1. Table Types

There are several types of tables in a citus cluster, each used for different purposes.

- Type 1: Distributed Tables.

The first type, and most common, is *distributed* tables. These appear to be normal tables to SQL statements, but are horizontally *partitioned* across worker nodes. See the [figure](#) below to learn more.

**Figure J.8. Parallel SELECT Diagram**

Here the rows of `table` are stored in tables `table_1001`, `table_1002`, etc. on the workers. The component worker tables are called *shards*.

citus runs not only SQL but DDL statements throughout a cluster, so changing the schema of a distributed table cascades to update all the table shards across workers.

To learn how to create a distributed table, see the [Creating and Modifying Distributed Objects \(DDL\)](#) section.

**Distribution Column.** citus uses algorithmic sharding to assign rows to shards. This means the assignment is made deterministically — in our case based on the value of a particular table column called the *distribution column*. The cluster administrator must designate this column when distributing a table. Making the right choice is important for performance and functionality, as described in the general topic of the [Choosing Distribution Column](#) section.

- Type 2: Reference Tables.

A reference table is a type of distributed table whose entire contents are concentrated into a single shard, which is replicated on every worker. Thus queries on any worker can access the reference information locally, without the network overhead of requesting rows from another node. Reference tables have no distribution column because there is no need to distinguish separate shards per row.

Reference tables are typically small and are used to store data that is relevant to queries running on any worker node. For example, enumerated values like order statuses or product categories.

When interacting with a reference table, we automatically perform [two-phase commits](#) on transactions. This means that citus makes sure your data is always in a consistent state, regardless of whether you are writing, modifying or deleting it.

The [Reference Tables](#) section talks more about these tables and how to create them.

- Type 3: Local Tables.

When you use citus, the coordinator node you connect to and interact with is a regular Postgres Pro database with the citus extension installed. Thus you can create ordinary tables and choose not to shard them. This is useful for small administrative tables that do not participate in join queries. An example would be users table for application login and authentication.

Creating standard Postgres Pro tables is easy because it is the default. It is what you get when you run `CREATE TABLE`. In almost every citus deployment we see standard Postgres Pro tables co-existing with distributed and reference tables. Indeed, citus itself uses local tables to hold cluster metadata, as mentioned earlier.

- Type 4: Local Managed Tables.

When the [citus.enable\\_local\\_reference\\_table\\_foreign\\_keys](#) configuration parameter is enabled, citus may automatically add local tables to metadata if a foreign key reference exists between a local table and a reference table. Additionally this tables can be manually created by calling the [citus\\_add\\_local\\_table\\_to\\_metadata](#) function on regular local tables. Tables present in metadata are considered managed tables and can be queried from any node, citus will know to route to the coordinator to obtain data from the local managed table. Such tables are displayed as local in the [citus\\_tables](#) view.

- Type 5: Schema Tables.

When using [schema-based sharding](#), distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas are automatically converted to co-located distributed tables without a shard key. Such tables are considered schema tables and are displayed as schema in the [citus\\_tables](#) view.

#### J.5.6.3.2. Shards

The previous section described a shard as containing a subset of the rows of a distributed table in a smaller table within a worker node. This section gets more into the technical details.

The `pg_dist_shard` metadata table on the coordinator contains a row for each shard of each distributed table in the system. The row matches a `shardid` with a range of integers in a hash space (`shardminvalue`, `shardmaxvalue`):

```
SELECT * FROM pg_dist_shard;
 logicalrelid | shardid | shardstorage | shardminvalue | shardmaxvalue
-----+-----+-----+-----+-----
 github_events | 102026 | t             | 268435456     | 402653183
 github_events | 102027 | t             | 402653184     | 536870911
 github_events | 102028 | t             | 536870912     | 671088639
 github_events | 102029 | t             | 671088640     | 805306367
(4 rows)
```

If the coordinator node wants to determine which shard holds a row of `github_events`, it hashes the value of the distribution column in the row, and checks which shard's range contains the hashed value. (The ranges are defined so that the image of the hash function is their disjoint union.)

#### J.5.6.3.2.1. Shard Placements

Suppose that shard 102027 is associated with the row in question. This means the row should be read or written to a table called `github_events_102027` in one of the workers. Which worker? That is determined entirely by the metadata tables, and the mapping of shard to worker is known as the *shard placement*.

Joining some [metadata tables](#) gives us the answer. These are the types of lookups that the coordinator does to route queries. It rewrites queries into fragments that refer to the specific tables like `github_events_102027`, and runs those fragments on the appropriate workers.

```
SELECT
    shardid,
    node.nodename,
    node.nodeport
FROM pg_dist_placement placement
JOIN pg_dist_node node
    ON placement.groupid = node.groupid
    AND node.noderole = 'primary'::noderole
WHERE shardid = 102027;
```

| shardid | nodename  | nodeport |
|---------|-----------|----------|
| 102027  | localhost | 5433     |

In our example of `github_events` there were four shards. The number of shards is configurable per table at the time of its distribution across the cluster. The best choice of shard count depends on your use case, see the [Shard Count](#) section.

Finally note that citus allows shards to be replicated for protection against data loss using Postgres Pro streaming replication to back up the entire database of each node to a follower database. This is transparent and does not require the involvement of citus metadata tables.

#### J.5.6.3.3. Co-Location

Since shards can be placed on nodes as desired, it makes sense to place shards containing related rows of related tables together on the same nodes. That way join queries between them can avoid sending as much information over the network, and can be performed inside a single citus node.

One example is a database with `stores`, `products`, and `purchases`. If all three tables contain — and are distributed by — the `store_id` column, then all queries restricted to a single store can run efficiently on a single worker node. This is true even when the queries involve any combination of these tables.

For the full explanation and examples of this concept, see the [Table Co-Location](#) section.

#### J.5.6.3.4. Parallelism

Spreading queries across multiple computers allows more queries to run at once, and allows processing speed to scale by adding new computers to the cluster. Additionally splitting a single query into fragments as described in the previous section boosts the processing power devoted to it. The latter situation achieves the greatest *parallelism*, meaning utilization of CPU cores.

Queries reading or affecting shards spread evenly across many nodes are able to run at “real-time” speed. Note that the results of the query still need to pass back through the coordinator node, so the speedup is most apparent when the final results are compact, such as aggregate functions like counting and descriptive statistics.

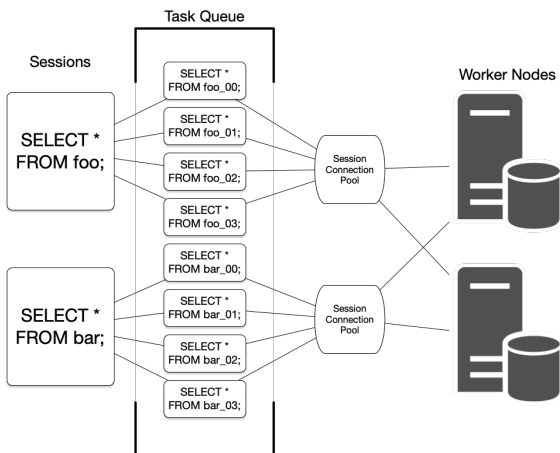

The [Query Processing](#) section explains more about how queries are broken into fragments and how their execution is managed.

#### J.5.6.4. Query Execution

When executing multi-shard queries, citus must balance the gains from parallelism with the overhead from database connections (network latency and worker node resource usage). To configure citus query execution for best results with your database workload, it helps to understand how citus manages and conserves database connections between the coordinator node and worker nodes.

citus transforms each incoming multi-shard query session into per-shard queries called tasks. It queues the tasks, and runs them once it is able to obtain connections to the relevant worker nodes. For queries on distributed tables `foo` and `bar`, see the [connection management diagram](#) below.

**Figure J.9. Executor Overview**

The coordinator node has a connection pool for each session. Each query (such as `SELECT * FROM foo` in the diagram) is limited to opening at most simultaneous connections for its tasks per worker set in the [citus.max\\_adaptive\\_executor\\_pool\\_size](#) configuration parameter. It is configurable at the session level, for priority management.

It can be faster to execute short tasks sequentially over the same connection rather than establishing new connections for them in parallel. Long running tasks, on the other hand, benefit from more immediate parallelism.

To balance the needs of short and long tasks, citus uses the [citus.executor\\_slow\\_start\\_interval](#) configuration parameter. It specifies a delay between connection attempts for the tasks in a multi-shard query. When a query first queues tasks, the tasks can acquire just one connection. At the end of each interval where there are pending connections, citus increases the number of simultaneous connections it will open. The slow start behavior can be disabled entirely by setting the GUC to 0.

When a task finishes using a connection, the session pool will hold the connection open for later. Caching the connection avoids the overhead of connection reestablishment between coordinator and worker.

However, each pool will hold no more than the number of idle connections open at once set by the `citus.max_cached_conns_per_worker` configuration parameter, to limit idle connection resource usage in the worker.

Finally, the `citus.max_shared_pool_size` configuration parameter acts as a fail-safe. It limits the total connections per worker between all tasks.

For recommendations about tuning these parameters to match your workload, see the [Connection Management](#) section.

## J.5.7. Develop

### J.5.7.1. Determining Application Type

Running efficient queries on a citus cluster requires that data be properly distributed across computers. This varies by the type of application and its query patterns.

There are broadly two kinds of applications that work very well on citus. The first step in data modeling is to identify which of them more closely resembles your application.

#### J.5.7.1.1. At a Glance

| Multi-Tenant Applications                                | Real-Time Applications                                |
|----------------------------------------------------------|-------------------------------------------------------|
| Sometimes dozens or hundreds of tables in schema         | Small number of tables                                |
| Queries relating to one tenant (company/store) at a time | Relatively simple analytics queries with aggregations |
| OLTP workloads for serving web clients                   | High ingest volume of mostly immutable data           |
| OLAP workloads that serve per-tenant analytical queries  | Often centering around a big table of events          |

#### J.5.7.1.2. Examples and Characteristics

##### J.5.7.1.2.1. Multi-Tenant Applications

These are typically SaaS applications that serve other companies, accounts, or organizations. Most SaaS applications are inherently relational. They have a natural dimension on which to distribute data across nodes: just shard by `tenant_id`.

`citus` enables you to scale out your database to millions of tenants without having to re-architect your application. You can keep the relational semantics you need, like joins, foreign key constraints, transactions, ACID, and consistency.

- **Examples:** Websites, which host store-fronts for other businesses, such as a digital marketing solution, or a sales automation tool.
- **Characteristics:** Queries relating to a single tenant rather than joining information across tenants. This includes OLTP workloads for serving web clients, and OLAP workloads that serve per-tenant analytical queries. Having dozens or hundreds of tables in your database schema is also an indicator for the multi-tenant data model.

Scaling a multi-tenant app with `citus` also requires minimal changes to application code. We have support for popular frameworks like Ruby on Rails and Django.

##### J.5.7.1.2.2. Real-Time Analytics

Applications needing massive parallelism, coordinating hundreds of cores for fast results to numerical, statistical, or counting queries. By sharding and parallelizing SQL queries across multiple nodes, `citus` makes it possible to perform real-time queries across billions of records in under a second.

- **Examples:** Customer-facing analytics dashboards requiring sub-second response times.

- **Characteristics:** Few tables, often centering around a big table of device-, site- or user-events and requiring high ingest volume of mostly immutable data. Relatively simple (but computationally intensive) analytics queries involving several aggregations and `GROUP BY` operations.

If your situation resembles either cases above, then the next step is to decide how to shard your data in the citus cluster. As explained in the [Architecture Concepts](#) section, citus assigns table rows to shards according to the hashed value of the table distribution column. The database administrator's choice of distribution columns needs to match the access patterns of typical queries to ensure performance.

### J.5.7.2. Choosing Distribution Column

citus uses the distribution column in distributed tables to assign table rows to shards. Choosing the distribution column for each table is **one of the most important** modeling decisions because it determines how data is spread across nodes.

If the distribution columns are chosen correctly, then related data will group together on the same physical nodes, making queries fast and adding support for all SQL features. If the columns are chosen incorrectly, the system will run needlessly slowly, and will not be able to support all SQL features across nodes.

This section gives distribution column tips for the two most common citus scenarios. It concludes by going in-depth on “co-location”, the desirable grouping of data on nodes.

#### J.5.7.2.1. Multi-Tenant Apps

The multi-tenant architecture uses a form of hierarchical database modeling to distribute queries across nodes in the distributed cluster. The top of the data hierarchy is known as the `tenant_id`, and needs to be stored in a column on each table. citus inspects queries to see which `tenant_id` they involve and routes the query to a single worker node for processing, specifically the node that holds the data shard associated with the `tenant_id`. Running a query with all relevant data placed on the same node is called [co-location](#).

The following [diagram](#) illustrates co-location in the multi-tenant data model. It contains two tables, Accounts and Campaigns, each distributed by `account_id`. The shaded boxes represent shards, each of whose color represents which worker node contains it. Green shards are stored together on one worker node, and blue on another. Notice how a join query between Accounts and Campaigns would have all the necessary data together on one node when restricting both tables to the same `account_id`.

**Figure J.10. Multi-Tenant Co-Location**

To apply this design in your own schema the first step is identifying what constitutes a tenant in your application. Common instances include company, account, organization, or customer. The column name will be something like `company_id` or `customer_id`. Examine each of your queries and ask yourself: would it work if it had additional `WHERE` clauses to restrict all tables involved to rows with the same `tenant_id`? Queries in the multi-tenant model are usually scoped to a tenant, for instance, queries on sales or inventory would be scoped within a certain store.

Best practices are as follows:

- **Partition distributed tables by the common `tenant_id` column.** For instance, in a SaaS application where tenants are companies, the `tenant_id` will likely be `company_id`.
- **Convert small cross-tenant tables to reference tables.** When multiple tenants share a small table of information, distribute it as a [reference table](#).
- **Restrict filter all application queries by `tenant_id`.** Each query should request information for one tenant at a time.

Consult the [Multi-Tenant Applications](#) section for a detailed example of building this kind of application.

#### J.5.7.2.2. Real-Time Apps

While the multi-tenant architecture introduces a hierarchical structure and uses data co-location to route queries per tenant, real-time architectures depend on specific distribution properties of their data to achieve highly parallel processing.

We use “entity ID” as a term for distribution columns in the real-time model, as opposed to tenant IDs in the multi-tenant model. Typical entities are users, hosts, or devices.

Real-time queries typically ask for numeric aggregates grouped by date or category. citus sends these queries to each shard for partial results and assembles the final answer on the coordinator node. Queries run fastest when as many nodes contribute as possible, and when no single node must do a disproportionate amount of work.

Best practices are as follows:

- **Choose a column with high cardinality as the distribution column.** For comparison, a “status” field on an order table with values “new”, “paid”, and “shipped” is a poor choice of distribution column because it assumes only those few values. The number of distinct values limits the number of shards that can hold the data, and the number of nodes that can process it. Among columns with high cardinality, it is good additionally to choose those that are frequently used in group-by clauses or as join keys.
- **Choose a column with even distribution.** If you distribute a table on a column skewed to certain common values, then data in the table will tend to accumulate in certain shards. The nodes holding those shards will end up doing more work than other nodes.
- **Distribute fact and dimension tables on their common columns.** Your fact table can have only one distribution key. Tables that join on another key will not be co-located with the fact table. Choose one dimension to co-locate based on how frequently it is joined and the size of the joining rows.
- **Change some dimension tables into reference tables.** If a dimension table cannot be co-located with the fact table, you can improve query performance by distributing copies of the dimension table to all of the nodes in the form of a [reference table](#).

Consult the [Real-Time Dashboards](#) section for a detailed example of building this kind of application.

#### J.5.7.2.3. Timeseries Data

In a time-series workload, applications query recent information while archiving old information.

The most common mistake in modeling timeseries information in citus is using the timestamp itself as a distribution column. A hash distribution based on time will distribute times seemingly at random into different shards rather than keeping ranges of time together in shards. However, queries involving time generally reference ranges of time (for example, the most recent data), so such a hash distribution would lead to network overhead.

Best practices are as follows:

- **Do not choose a timestamp as the distribution column.** Choose a different distribution column. In a multi-tenant app, use the `tenant_id` or in a real-time app use the `entity_id`.

- **Use Postgres Pro table partitioning for time instead.** Use table partitioning to break a big table of time-ordered data into multiple inherited tables with each containing different time ranges. Distributing a Postgres Pro partitioned table in citus creates shards for the inherited tables.

Consult the [Timeseries Data](#) section for a detailed example of building this kind of application.

#### J.5.7.2.4. Table Co-Location

Relational databases are the first choice of data store for many applications due to their enormous flexibility and reliability. Historically the one criticism of relational databases is that they can run on only a single computer, which creates inherent limitations when data storage needs outpace server improvements. The solution to rapidly scaling databases is to distribute them, but this creates a performance problem of its own: relational operations such as joins then need to cross the network boundary. Co-location is the practice of dividing data tactically, where one keeps related information on the same computers to enable efficient relational operations, but takes advantage of the horizontal scalability for the whole dataset.

The principle of data co-location is that all tables in the database have a common distribution column and are sharded across computers in the same way, such that rows with the same distribution column value are always on the same computer, even across different tables. As long as the distribution column provides a meaningful grouping of data, relational operations can be performed within the groups.

##### J.5.7.2.4.1. Data Co-Location in citus for Hash-Distributed Tables

The citus extension for Postgres Pro is unique in being able to form a distributed database of databases. Every node in a citus cluster is a fully functional Postgres Pro database and the extension adds the experience of a single homogenous database on top. While it does not provide the full functionality of Postgres Pro in a distributed way, in many cases it can take full advantage of features offered by Postgres Pro on a single computer through co-location, including full SQL support, transactions, and foreign keys.

In citus a row is stored in a shard if the hash of the value in the distribution column falls within the shard hash range. To ensure co-location, shards with the same hash range are always placed on the same node even after rebalance operations, such that equal distribution column values are always on the same node across tables. See the [figure](#) below to learn more.

**Figure J.11. Co-Location Shards**

|        | events shards |                                       | page shards |                                       |
|--------|---------------|---------------------------------------|-------------|---------------------------------------|
|        | shard         | hash range                            | shard       | hash range                            |
| NODE 1 | 1             | $-2147483648 \leq x \leq -1073741825$ | 5           | $-2147483648 \leq x \leq -1073741825$ |
|        | 2             | $-1073741824 \leq x \leq -1$          | 6           | $-1073741824 \leq x \leq -1$          |
| NODE 2 | 3             | $0 \leq x \leq 1073741823$            | 7           | $0 \leq x \leq 1073741823$            |
|        | 4             | $1073741824 \leq x \leq 2147483647$   | 8           | $1073741824 \leq x \leq 2147483647$   |

$x = \text{hash}(\text{distribution\_column})$

A distribution column that we have found to work well in practice is `tenant_id` in multi-tenant applications. For example, SaaS applications typically have many tenants, but every query they make is specific to a particular tenant. While one option is providing a database or schema for every tenant, it is often costly and impractical as there can be many operations that span across users (data loading, migrations, aggregations, analytics, schema changes, backups, etc). That becomes harder to manage as the number of tenants grows.

##### J.5.7.2.4.2. Practical Example of Co-Location

Consider the following tables, which might be part of a multi-tenant web analytics SaaS:

```
CREATE TABLE event (
  tenant_id int,
  event_id bigint,
  page_id int,
  payload jsonb,
```

```
    primary key (tenant_id, event_id)
);

CREATE TABLE page (
    tenant_id int,
    page_id int,
    path text,
    primary key (tenant_id, page_id)
);
```

Now we want to answer queries that may be issued by a customer-facing dashboard, such as: “Return the number of visits in the past week for all pages starting with `/blog` in tenant six”.

#### J.5.7.2.4.3. Using Regular Postgres Pro Tables

If our data was in a single Postgres Pro node, we could easily express our query using the rich set of relational operations offered by SQL:

```
SELECT page_id, count(event_id)
FROM
    page
LEFT JOIN (
    SELECT * FROM event
    WHERE (payload->>'time')::timestamp >= now() - interval '1 week'
) recent
USING (tenant_id, page_id)
WHERE tenant_id = 6 AND path LIKE '/blog%'
GROUP BY page_id;
```

As long as the *working set* for this query fits in memory, this is an appropriate solution for many applications since it offers maximum flexibility. However, even if you do not need to scale yet, it can be useful to consider the implications of scaling out on your data model.

#### J.5.7.2.4.4. Distributing Tables by ID

As the number of tenants and the data stored for each tenant grows, query times will typically go up as the working set no longer fits in memory or CPU becomes a bottleneck. In this case, we can shard the data across many nodes using `citus`. The first and the most important choice we need to make when sharding is the distribution column. Let's start with a naive choice of using `event_id` for the `event` table and `page_id` for the `page` table:

```
-- Naively use event_id and page_id as distribution columns

SELECT create_distributed_table('event', 'event_id');
SELECT create_distributed_table('page', 'page_id');
```

Given that the data is dispersed across different workers, we cannot simply perform a join as we would on a single Postgres Pro node. Instead, we will need to issue two queries:

Across all shards of the `page` table (Q1):

```
SELECT page_id FROM page WHERE path LIKE '/blog%' AND tenant_id = 6;
```

Across all shards of the `event` table (Q2):

```
SELECT page_id, count(*) AS count
FROM event
WHERE page_id IN (/*...page IDs from first query...*/)
    AND tenant_id = 6
    AND (payload->>'time')::date >= now() - interval '1 week'
GROUP BY page_id ORDER BY count DESC LIMIT 10;
```

Afterwards, the results from the two steps need to be combined by the application.

The data required to answer the query is scattered across the shards on the different nodes and each of those shards will need to be queried. See the [figure](#) below to learn more.

**Figure J.12. Co-Location With Inefficient Queries**

In this case the data distribution creates substantial drawbacks:

- Overhead from querying each shard, running multiple queries.
- Overhead of Q1 returning many rows to the client.
- Q2 becomes very large.
- The need to write queries in multiple steps, combine results, requires changes in the application.

A potential upside of the relevant data being dispersed is that the queries can be parallelised, which Citus will do. However, this is only beneficial if the amount of work that the query does is substantially greater than the overhead of querying many shards. It is generally better to avoid doing such heavy lifting directly from the application, for example, by [pre-aggregating](#) the data.

#### J.5.7.2.4.5. Distributing Tables by Tenant

Looking at our query again, we can see that all the rows that the query needs have one dimension in common: `tenant_id`. The dashboard will only ever query for a tenant's own data. That means that if data for the same tenant is always co-located on a single Postgres Pro node, our original query could be answered in a single step by that node by performing a join on `tenant_id` and `page_id`.

In Citus, rows with the same distribution column value are guaranteed to be on the same node. Each shard in a distributed table effectively has a set of co-located shards from other distributed tables that contain the same distribution column values (data for the same tenant). Starting over, we can create our tables with `tenant_id` as the distribution column.

```
-- Co-locate tables by using a common distribution column
SELECT create_distributed_table('event', 'tenant_id');
SELECT create_distributed_table('page', 'tenant_id', colocate_with => 'event');
```

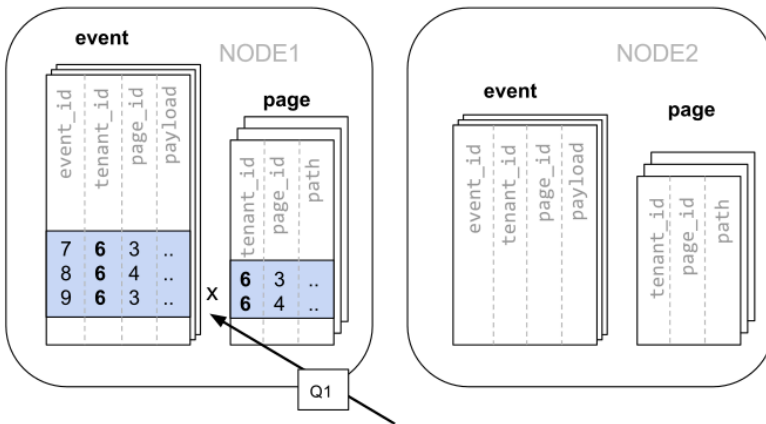

In this case, Citus can answer the same query that you would run on a single Postgres Pro node without modification (Q1):

```
SELECT page_id, count(event_id)
FROM
  page
LEFT JOIN (
  SELECT * FROM event
  WHERE (payload->>'time')::timestampz >= now() - interval '1 week'
) recent
USING (tenant_id, page_id)
WHERE tenant_id = 6 AND path LIKE '/blog%'
GROUP BY page_id;
```

Because of the `tenant_id` filter and join on `tenant_id`, Citus knows that the entire query can be answered using the set of co-located shards that contain the data for that particular tenant, and the Postgres Pro

node can answer the query in a single step, which enables full SQL support. See the [figure](#) below to learn more.

**Figure J.13. Co-Location With Better Queries**

In some cases, queries and table schemas will require minor modifications to ensure that the `tenant_id` is always included in unique constraints and join conditions. However, this is usually a straightforward change, and the extensive rewrite that would be required without having co-location is avoided.

While the example above queries just one node because there is a specific `tenant_id = 6` filter, co-location also allows us to efficiently perform distributed joins on `tenant_id` across all nodes, be it with SQL limitations.

#### J.5.7.2.4.6. Co-Location Means Better Feature Support

The full list of citus features that are unlocked by co-location are:

- Full SQL support for queries on a single set of co-located shards.
- Multi-statement transaction support for modifications on a single set of co-located shards.
- Aggregation through `INSERT...SELECT`.
- Foreign keys.
- Distributed outer joins.
- Pushdown CTEs.

Data co-location is a powerful technique for providing both horizontal scale and support to relational data models. The cost of migrating or building applications using a distributed database that enables relational operations through co-location is often substantially lower than moving to a restrictive data model (e.g. NoSQL) and, unlike a single-node database, it can scale out with the size of your business. For more information about migrating an existing database, see the [Migrating an Existing App](#).

#### J.5.7.2.4.7. Query Performance

citus parallelizes incoming queries by breaking it into multiple fragment queries (“tasks”), which run on the worker shards in parallel. This allows citus to utilize the processing power of all the nodes in the cluster and also of individual cores on each node for each query. Due to this parallelization, you can get performance, which is cumulative of the computing power of all of the cores in the cluster leading to a dramatic decrease in query times versus Postgres Pro on a single server.

citus employs a two stage optimizer when planning SQL queries. The first phase involves converting the SQL queries into their commutative and associative form so that they can be pushed down and run on the workers in parallel. As discussed in previous sections, choosing the right distribution column and distribution method allows the distributed query planner to apply several optimizations to the queries. This can have a significant impact on query performance due to reduced network I/O.

The distributed executor of the citus extension then takes these individual query fragments and sends them to worker Postgres Pro instances. There are several aspects of both the distributed planner and the executor, which can be tuned in order to improve performance. When these individual query fragments are sent to the workers, the second phase of query optimization kicks in. The workers are simply running extended Postgres Pro servers and they apply Postgres Pro standard planning and execution logic to run these fragment SQL queries. Therefore, any optimization that helps Postgres Pro also helps citus. Postgres Pro by default comes with conservative resource settings; and therefore optimizing these configuration settings can improve query times significantly.

We discuss the relevant performance tuning steps in the [Query Performance Tuning](#) section.

### J.5.7.3. Migrating an Existing App

Migrating an existing application to citus sometimes requires adjusting the schema and queries for optimal performance. citus extends Postgres Pro with distributed functionality, but [row-based sharding](#) is not a drop-in replacement that scales out all workloads. A performant citus cluster involves thinking about the data model, tooling, and choice of SQL features used.

There is another mode of operation in citus called [schema-based sharding](#), and while [row-based sharding](#) results in best performance and hardware efficiency, see [schema-based sharding](#) if you are in a need for a more drop-in approach.

1. The first steps are to optimize the existing database schema so that it can work efficiently across multiple computers.
  - a. [Identify Distribution Strategy](#)
    - i. [Pick Distribution Key](#)
    - ii. [Identify Types of Tables](#)
  - b. [Prepare Source Tables for Migration](#)
    - i. [Add Distribution Keys](#)
    - ii. [Backfill Newly Created Columns](#)
2. Next, update application code and queries to deal with the schema changes.
  - a. [Prepare Application for citus](#)
    - i. [Set Up Development citus Cluster](#)
    - ii. [Add Distribution Key to Queries](#)
    - iii. [Enable Secure Connections](#)
    - iv. [Check for Cross-Node Traffic](#)
3. After testing the changes in a development environment, the last step is to migrate production data to a citus cluster and switch over the production app. We have techniques to minimize downtime for this step.
  - a. [Migrate Production Data](#)
    - i. [Database Migration](#)

#### J.5.7.3.1. Identify Distribution Strategy

##### J.5.7.3.1.1. Pick Distribution Key

The first step in migrating to citus is identifying suitable distribution keys and planning table distribution accordingly. In multi-tenant applications this will typically be an internal identifier for tenants. We typically refer to it as the `tenant_id`. The use cases may vary, so we advise being thorough on this step.

For guidance, consult these sections:

1. [Determining Application Type](#)

## 2. Choosing Distribution Column

Review your environment to be sure that the ideal distribution key is chosen. To do so, examine schema layouts, larger tables, long-running and/or problematic queries, standard use cases, and more.

### J.5.7.3.1.2. Identify Types of Tables

Once a distribution key is identified, review the schema to identify how each table will be handled and whether any modifications to table layouts will be required.

Tables will generally fall into one of the following categories:

- Ready for distribution. These tables already contain the distribution key, and are ready for distribution.
- Needs backfill. These tables can be logically distributed by the chosen key but do not contain a column directly referencing it. The tables will be modified later to add the column.
- Reference table. These tables are typically small, do not contain the distribution key, are commonly joined by distributed tables, and/or are shared across tenants. A copy of each of these tables will be maintained on all nodes. Common examples include country code lookups, product categories, and the like.
- Local table. These are typically not joined to other tables, and do not contain the distribution key. They are maintained exclusively on the coordinator node. Common examples include admin user lookups and other utility tables.

Consider an example multi-tenant application similar to Etsy or Shopify where each tenant is a store. A simplified schema is presented in the [diagram](#) below. (Underlined items are primary keys, italicized items are foreign keys.)

**Figure J.14. Simplified Schema Example**

In this example stores are a natural tenant. The `tenant_id` is in this case the `store_id`. After distributing tables in the cluster, we want rows relating to the same store to reside together on the same nodes.

### J.5.7.3.2. Prepare Source Tables for Migration

Once the scope of needed database changes is identified, the next major step is to modify the data structure for the application's existing database. First, tables requiring backfill are modified to add a column for the distribution key.

#### J.5.7.3.2.1. Add Distribution Keys

In our storefront example the stores and products tables have a `store_id` and are ready for distribution. Being normalized, the `line_items` table lacks `store_id`. If we want to distribute by `store_id`, the table needs this column.

```
-- Denormalize line_items by including store_id
```

```
ALTER TABLE line_items ADD COLUMN store_id uuid;
```

Be sure to check that the distribution column has the same type in all tables, e.g. do not mix `int` and `bigint`. The column types must match to ensure proper data co-location.

#### J.5.7.3.2.2. Backfill Newly Created Columns

Once the schema is updated, backfill missing values for the `tenant_id` column in tables where the column was added. In our example `line_items` requires values for `store_id`.

We backfill the table by obtaining the missing values from a join query with orders:

```
UPDATE line_items
  SET store_id = orders.store_id
  FROM line_items
 INNER JOIN orders
 WHERE line_items.order_id = orders.order_id;
```

Doing the whole table at once may cause too much load on the database and disrupt other queries. The backfill can be done more slowly instead. One way to do that is to make a function that backfills small batches at a time, then call the function repeatedly with [pg\\_cron](#).

```
-- The function to backfill up to one
-- thousand rows from line_items
```

```
CREATE FUNCTION backfill_batch()
RETURNS void LANGUAGE sql AS $$
  WITH batch AS (
    SELECT line_items_id, order_id
      FROM line_items
     WHERE store_id IS NULL
    LIMIT 1000
      FOR UPDATE
      SKIP LOCKED
  )
  UPDATE line_items AS li
    SET store_id = orders.store_id
  FROM batch, orders
 WHERE batch.line_item_id = li.line_item_id
    AND batch.order_id = orders.order_id;
$$;
```

```
-- Run the function every quarter hour
SELECT cron.schedule('* / 15 * * * *', 'SELECT backfill_batch()');
```

```
-- Note the return value of cron.schedule
```

Once the backfill is caught up, the cron job can be disabled:

```
-- Assuming 42 is the job id returned
-- from cron.schedule
```

```
SELECT cron.unschedule(42);
```

### J.5.7.3.3. Prepare Application for citus

#### J.5.7.3.3.1. Set Up Development citus Cluster

When modifying the application to work with citus, you will need a database to test against. Follow the instructions in the [Installing citus on a Single Node](#) section to set up the extension.

Next dump a copy of the schema from your application's original database and restore the schema in the new development database.

```
# get schema from source db

pg_dump \
  --format=plain \
  --no-owner \
  --schema-only \
  --file=schema.sql \
  --schema=target_schema \
  postgres://user:pass@host:5432/db

# load schema into test db

psql postgres://user:pass@testhost:5432/db -f schema.sql
```

The schema should include a distribution key (`tenant_id`) in all tables you wish to distribute. Before running [pg\\_dump](#) for the schema, be sure to [prepare source tables for migration](#).

#### Include Distribution Column in Keys

citus [cannot enforce](#) uniqueness constraints unless a unique index or primary key contains the distribution column. Thus we must modify primary and foreign keys in our example to include `store_id`.

Some of the libraries listed in the next section are able to help migrate the database schema to include the distribution column in keys. However, here is an example of the underlying SQL commands to turn the simple keys composite in the development database:

```
BEGIN;

-- Drop simple primary keys (cascades to foreign keys)

ALTER TABLE products    DROP CONSTRAINT products_pkey CASCADE;
ALTER TABLE orders      DROP CONSTRAINT orders_pkey CASCADE;
ALTER TABLE line_items  DROP CONSTRAINT line_items_pkey CASCADE;

-- Recreate primary keys to include would-be distribution column

ALTER TABLE products    ADD PRIMARY KEY (store_id, product_id);
ALTER TABLE orders      ADD PRIMARY KEY (store_id, order_id);
ALTER TABLE line_items  ADD PRIMARY KEY (store_id, line_item_id);

-- Recreate foreign keys to include would-be distribution column

ALTER TABLE line_items ADD CONSTRAINT line_items_store_fkey
  FOREIGN KEY (store_id) REFERENCES stores (store_id);
ALTER TABLE line_items ADD CONSTRAINT line_items_product_fkey
  FOREIGN KEY (store_id, product_id) REFERENCES products (store_id, product_id);
ALTER TABLE line_items ADD CONSTRAINT line_items_order_fkey
  FOREIGN KEY (store_id, order_id) REFERENCES orders (store_id, order_id);

COMMIT;
```

Thus completed, our schema from the previous section will look like [this](#) (Underlined items are primary keys, italicized items are foreign keys.):

**Figure J.15. Simplified Schema Example**

Be sure to modify data flows to add keys to incoming data.

#### J.5.7.3.3.2. Add Distribution Key to Queries

Once the distribution key is present on all appropriate tables, the application needs to include it in queries. Take the following steps using a copy of the application running in a development environment, and testing against a citus back-end. After the application is working with the extension we will see how to migrate production data from the source database into a real citus cluster.

- Application code and any other ingestion processes that write to the tables should be updated to include the new columns.
- Running the application test suite against the modified schema on citus is a good way to determine which areas of the code need to be modified.
- It is a good idea to enable database logging. The logs can help uncover stray cross-shard queries in a multi-tenant app that should be converted to per-tenant queries.

Cross-shard queries are supported, but in a multi-tenant application most queries should be targeted to a single node. For simple `SELECT`, `UPDATE`, and `DELETE` queries this means that the `WHERE` clause should filter by `tenant_id`. citus can then run these queries efficiently on a single node.

There are helper libraries for a number of popular application frameworks that make it easy to include `tenant_id` in queries:

- [Ruby on Rails](#)
- [Django Multitenant](#)
- [ASP.NET](#)
- [Java Hibernate](#)

It is possible to use the libraries for database writes first (including data ingestion) and later for read queries. The [activerecord-multi-tenant](#) gem, for instance, has a [write-only mode](#) that modifies only the write queries.

#### Other (SQL Principles)

If you are using a different ORM than those above or executing multi-tenant queries more directly in SQL, follow these general principles. We will use our earlier example of the e-commerce application.

Suppose we want to get the details for an order. Distributed queries that filter on the `tenant_id` run most efficiently in multi-tenant apps, so the change below makes the query faster (while both queries return the same results):

```
-- Before
SELECT *
  FROM orders
 WHERE order_id = 123;

-- After
SELECT *
  FROM orders
 WHERE order_id = 123
    AND store_id = 42; -- <== added
```

The `tenant_id` column is not just beneficial but critical for `INSERT` statements. Inserts must include a value for the `tenant_id` column or else Citus will be unable to route the data to the correct shard and will raise an error.

Finally, when joining tables make sure to filter by `tenant_id` too. For instance, here is how to inspect how many “awesome wool pants” a given store has sold:

```
-- One way is to include store_id in the join and also
-- filter by it in one of the queries

SELECT sum(l.quantity)
  FROM line_items l
 INNER JOIN products p
    ON l.product_id = p.product_id
    AND l.store_id = p.store_id
 WHERE p.name='Awesome Wool Pants'
    AND l.store_id='8c69aa0d-3f13-4440-86ca-443566c1fc75'

-- Equivalently you omit store_id from the join condition
-- but filter both tables by it. This may be useful if
-- building the query in an ORM

SELECT sum(l.quantity)
  FROM line_items l
 INNER JOIN products p ON l.product_id = p.product_id
 WHERE p.name='Awesome Wool Pants'
    AND l.store_id='8c69aa0d-3f13-4440-86ca-443566c1fc75'
    AND p.store_id='8c69aa0d-3f13-4440-86ca-443566c1fc75'
```

#### J.5.7.3.3.3. Enable Secure Connections

Clients should connect to Citus with SSL to protect information and prevent man-in-the-middle attacks.

#### Check for Cross-Node Traffic

With large and complex application code-bases, certain queries generated by the application can often be overlooked and thus will not have the `tenant_id` filter on them. Citus parallel executor will still execute these queries successfully, and so, during testing, these queries remain hidden since the application still works fine. However, if a query does not contain the `tenant_id` filter, Citus executor will hit every shard in parallel, but only one will return any data. This consumes resources needlessly and may exhibit itself as a problem only when one moves to a higher-throughput production environment.

To prevent encountering such issues only after launching in production, one can set a config value to log queries, which hit more than one shard. In a properly configured and migrated multi-tenant application, each query should only hit one shard at a time.

During testing, one can configure the following:

```
-- Adjust for your own database's name of course
```

```
ALTER DATABASE citus SET citus.multi_task_query_log_level = 'error';
```

citus will then error out if it encounters queries that are going to hit more than one shard. Erroring out during testing allows the application developer to find and migrate such queries.

During a production launch, one can configure the same setting to log, instead of error out:

```
ALTER DATABASE citus SET citus.multi_task_query_log_level = 'log';
```

Visit the [citus.multi\\_task\\_query\\_log\\_level](#) section description to learn more about the supported values.

#### J.5.7.3.4. Migrate Production Data

At this time, having updated the database schema and application queries to work with citus, you are ready for the final step. It is time to migrate data to the citus cluster and cut over the application to its new database. The data migration procedure is presented in the [Database Migration](#) section.

##### J.5.7.3.4.1. Database Migration

For smaller environments that can tolerate a little downtime, use a simple [pg\\_dump/pg\\_restore](#) process. Here are the steps:

1. Save the database structure from your development database:

```
pg_dump \
  --format=plain \
  --no-owner \
  --schema-only \
  --file=schema.sql \
  --schema=target_schema \
  postgres://user:pass@host:5432/db
```

2. Connect to the citus cluster using psql and create a schema:

```
\i schema.sql
```

3. Call the [create\\_distributed\\_table](#) and [create\\_reference\\_table](#) functions. If you get an error about foreign keys, it is generally due to the order of operations. Drop foreign keys before distributing tables and then re-add them.
4. Put the application into maintenance mode and disable any other writes to the old database.
5. Save the data from the original production database to disk with pg\_dump:

```
pg_dump \
  --format=custom \
  --no-owner \
  --data-only \
  --file=data.dump \
  --schema=target_schema \
  postgres://user:pass@host:5432/db
```

6. Import into citus using pg\_restore:

```
# remember to use connection details for citus,
# not the source database
pg_restore \
  --host=host \
  --dbname=dbname \
  --username=username \
  data.dump
```

```
# it will prompt you for the connection password
```

7. Test application.

## J.5.7.4. SQL Reference

### J.5.7.4.1. Creating and Modifying Distributed Objects (DDL)

#### J.5.7.4.1.1. Creating and Distributing Schemas

citux supports [schema-based sharding](#), which allows a schema to be distributed. Distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas will be automatically converted to co-located distributed tables without a shard key.

There are two ways in which a schema can be distributed in citux:

- Manually by calling the [citux\\_schema\\_distribute](#) function:

```
SELECT citux_schema_distribute('user_service');
```

This method also allows you to convert existing regular schemas into distributed schemas.

#### Note

You can only distribute schemas that do not contain distributed and reference tables.

- Alternative approach is to enable the [citux.enable\\_schema\\_based\\_sharding](#) configuration parameter:

```
SET citux.enable_schema_based_sharding TO ON;
```

```
CREATE SCHEMA AUTHORIZATION user_service;
```

The parameter can be changed for the current session or permanently in `postgresql.conf`. With the parameter set to `ON`, all created schemas are distributed by default.

The process of distributing the schema will automatically assign and move it to an existing node in the cluster. The background shard rebalancer takes these schemas and all tables within them when rebalancing the cluster, performing the optimal moves, and migrating the schemas between the nodes in the cluster.

To convert a schema back into a regular Postgres Pro schema, use the [citux\\_schema\\_undistribute](#) function:

```
SELECT citux_schema_undistribute('user_service');
```

The tables and data in the `user_service` schema will be moved from the current node back to the coordinator node in the cluster.

#### J.5.7.4.1.2. Creating and Distributing Tables

To create a distributed table, you need to first define the table schema. To do so, you can define a table using the [CREATE TABLE](#) command in the same way as you would do with a regular Postgres Pro table.

```
CREATE TABLE github_events
(
    event_id bigint,
    event_type text,
    event_public boolean,
    repo_id bigint,
    payload jsonb,
    repo jsonb,
    actor jsonb,
    org jsonb,
    created_at timestamp
);
```

Next, you can use the [create\\_distributed\\_table](#) function to specify the table distribution column and create the worker shards.

```
SELECT create_distributed_table('github_events', 'repo_id');
```

This function informs citus that the `github_events` table should be distributed on the `repo_id` column (by hashing the column value). The function also creates shards on the worker nodes using the [citus.shard\\_count](#) configuration parameter.

This example would create a total of `citus.shard_count` number of shards where each shard owns a portion of a hash token space. Once the shards are created, this function saves all distributed metadata on the coordinator.

Each created shard is assigned a unique `shard_id`. Each shard is represented on the worker node as a regular Postgres Pro table with the `tablename_shardid` name where `tablename` is the name of the distributed table and `shardid` is the unique ID assigned to that shard. You can connect to the worker Postgres Pro instances to view or run commands on individual shards.

You are now ready to insert data into the distributed table and run queries on it. You can also learn more about the function used in this section in the [citus Utility Functions](#) section.

### Reference Tables

The above method distributes tables into multiple horizontal shards, but another possibility is distributing tables into a single shard and replicating the shard to every worker node. Tables distributed this way are called *reference tables*. They are used to store data that needs to be frequently accessed by multiple nodes in a cluster.

Common candidates for reference tables include:

- Smaller tables that need to join with larger distributed tables.
- Tables in multi-tenant apps that lack a `tenant_id` column or which are not associated with a tenant. (In some cases, to reduce migration effort, users might even choose to make reference tables out of tables associated with a tenant but which currently lack a tenant ID.)
- Tables that need unique constraints across multiple columns and are small enough.

For instance, suppose a multi-tenant eCommerce site needs to calculate sales tax for transactions in any of its stores. Tax information is not specific to any tenant. It makes sense to consolidate it in a shared table. A US-centric reference table might look like this:

```
-- A reference table
```

```
CREATE TABLE states (  
    code char(2) PRIMARY KEY,  
    full_name text NOT NULL,  
    general_sales_tax numeric(4,3)  
);
```

```
-- Distribute it to all workers
```

```
SELECT create_reference_table('states');
```

Now queries such as one calculating tax for a shopping cart can join on the `states` table with no network overhead and can add a foreign key to the state code for better validation.

In addition to distributing a table as a single replicated shard, the [create\\_reference\\_table](#) function marks it as a reference table in the citus metadata tables. citus automatically performs [two-phase commits](#) for modifications to tables marked this way, which provides strong consistency guarantees.

If you have an existing distributed table, you can change it to a reference table by running:

```
SELECT undistribute_table('table_name');  
SELECT create_reference_table('table_name');
```

For another example of using reference tables in a multi-tenant application, see the [Sharing Data Between Tenants](#) section.

### Distributing Coordinator Data

If an existing Postgres Pro database is converted into the coordinator node for a citus cluster, the data in its tables can be distributed efficiently and with minimal interruption to an application.

The [create\\_distributed\\_table](#) function described earlier works on both empty and non-empty tables and for the latter it automatically distributes table rows throughout the cluster. You will know if it does this by the presence of the following message: NOTICE: Copying data from local table.... For example:

```
CREATE TABLE series AS SELECT i FROM generate_series(1,1000000) i;
SELECT create_distributed_table('series', 'i');
NOTICE: Copying data from local table...
NOTICE: copying the data has completed
DETAIL: The local data in the table is no longer visible, but is still on disk.
HINT: To remove the local data, run: SELECT
truncate_local_data_after_distributing_table($$public.series$$)
create_distributed_table
-----

(1 row)
```

Writes on the table are blocked while the data is migrated, and pending writes are handled as distributed queries once the function commits. (If the function fails, then the queries become local again.) Reads can continue as normal and will become distributed queries once the function commits.

When distributing tables A and B, where A has a foreign key to B, distribute the key destination table B first. Doing it in the wrong order will cause an error:

```
ERROR: cannot create foreign key constraint
DETAIL: Referenced table must be a distributed table or a reference table.
```

If it is not possible to distribute in the correct order, then drop the foreign keys, distribute the tables, and recreate the foreign keys.

After the tables are distributed, use the [truncate\\_local\\_data\\_after\\_distributing\\_table](#) function to remove local data. Leftover local data in distributed tables is inaccessible to citus queries and can cause irrelevant constraint violations on the coordinator.

#### J.5.7.4.1.3. Co-Locating Tables

Co-location is the practice of dividing data tactically, keeping related information on the same computers to enable efficient relational operations, while taking advantage of the horizontal scalability for the whole dataset. For more information and examples, see the [Table Co-Location](#) section.

Tables are co-located in groups. To manually control a table's co-location group assignment use the optional `colocate_with` parameter of the [create\\_distributed\\_table](#) function. If you do not care about a table's co-location, then omit this parameter. It defaults to the value 'default', which groups the table with any other default co-location table having the same distribution column type and shard count. If you want to break or update this implicit co-location, you can use the [update\\_distributed\\_table\\_colocation](#) function.

```
-- These tables are implicitly co-located by using the same
-- distribution column type and shard count with the default
-- co-location group
```

```
SELECT create_distributed_table('A', 'some_int_col');
SELECT create_distributed_table('B', 'other_int_col');
```

When a new table is not related to others in its would-be implicit co-location group, specify `colocate_with => 'none'`.

```
-- Not co-located with other tables
```

```
SELECT create_distributed_table('A', 'foo', colocate_with => 'none');
```

Splitting unrelated tables into their own co-location groups will improve [shard rebalancing](#) performance, because shards in the same group have to be moved together.

When tables are indeed related (for instance when they will be joined), it can make sense to explicitly co-locate them. The gains of appropriate co-location are more important than any rebalancing overhead.

To explicitly co-locate multiple tables, distribute one and then put the others into its co-location group. For example:

```
-- Distribute stores
```

```
SELECT create_distributed_table('stores', 'store_id');
```

```
-- Add to the same group as stores
```

```
SELECT create_distributed_table('orders', 'store_id', colocate_with => 'stores');
```

```
SELECT create_distributed_table('products', 'store_id', colocate_with => 'stores');
```

Information about co-location groups is stored in the [pg\\_dist\\_colocation](#) table, while the [pg\\_dist\\_partition](#) table reveals which tables are assigned to which groups.

#### J.5.7.4.1.4. Dropping Tables

You can use the standard Postgres Pro `DROP TABLE` command to remove your distributed tables. As with regular tables, `DROP TABLE` removes any indexes, rules, triggers, and constraints that exist for the target table. In addition, it also drops the shards on the worker nodes and cleans up their metadata.

```
DROP TABLE github_events;
```

#### J.5.7.4.1.5. Modifying Tables

citus automatically propagates many kinds of DDL statements, which means that modifying a distributed table on the coordinator node will update shards on the workers too. Other DDL statements require manual propagation, and certain others are prohibited such as those which would modify a distribution column. Attempting to run DDL that is ineligible for automatic propagation will raise an error and leave tables on the coordinator node unchanged.

Here is a reference of the categories of DDL statements, which propagate. Note that automatic propagation can be enabled or disabled with the [citus.enable\\_ddl\\_propagation](#) configuration parameter.

#### Adding/Modifying Columns

citus propagates most [ALTER TABLE](#) commands automatically. Adding columns or changing their default values work as they would in a single-machine Postgres Pro database:

```
-- Adding a column
```

```
ALTER TABLE products ADD COLUMN description text;
```

```
-- Changing default value
```

```
ALTER TABLE products ALTER COLUMN price SET DEFAULT 7.77;
```

Significant changes to an existing column like renaming it or changing its data type are fine too. However, the data type of the [distribution column](#) cannot be altered. This column determines how table data distributes through the citus cluster, and modifying its data type would require moving the data.

Attempting to do so causes an error:

```
-- Assuming store_id is the distribution column
-- for products and that it has type integer
```

```
ALTER TABLE products
```

```
ALTER COLUMN store_id TYPE text;

/*
ERROR:  cannot execute ALTER TABLE command involving partition column
*/
```

As a workaround, you can consider changing the distribution column using the [alter\\_distributed\\_table](#) function, updating it, and changing it back.

### Adding/Removing Constraints

Using citus allows you to continue to enjoy the safety of a relational database, including database [constraints](#). Due to the nature of distributed systems, citus will not cross-reference uniqueness constraints or referential integrity between worker nodes.

To set up a foreign key between co-located distributed tables, always include the distribution column in the key. This may involve making the key compound.

Foreign keys may be created in these situations:

- between two local (non-distributed) tables,
- between two reference tables,
- between reference tables and local tables (by default enabled via the [citus.enable\\_local\\_reference\\_table\\_foreign\\_keys](#) configuration parameter),
- between two [co-located](#) distributed tables when the key includes the distribution column, or
- as a distributed table referencing a [reference table](#).

Foreign keys from reference tables to distributed tables are not supported.

citus supports all [referential actions](#) on foreign keys from local to reference tables but does not support ON DELETE/ON UPDATE CASCADE in the reverse direction (reference to local).

### Note

Primary keys and uniqueness constraints must include the distribution column. Adding them to a non-distribution column will generate the [creating unique indexes on non-partition columns is currently unsupported](#) error.

This example shows how to create primary and foreign keys on distributed tables:

```
--
-- Adding a primary key
-- -----

-- We will distribute these tables on the account_id. The ads and clicks
-- tables must use compound keys that include account_id

ALTER TABLE accounts ADD PRIMARY KEY (id);
ALTER TABLE ads ADD PRIMARY KEY (account_id, id);
ALTER TABLE clicks ADD PRIMARY KEY (account_id, id);

-- Next distribute the tables

SELECT create_distributed_table('accounts', 'id');
SELECT create_distributed_table('ads',      'account_id');
SELECT create_distributed_table('clicks',   'account_id');

--
-- Adding foreign keys
```

```
-- -----
-- Note that this can happen before or after distribution, as long as
-- there exists a uniqueness constraint on the target column(s), which
-- can only be enforced before distribution
```

```
ALTER TABLE ads ADD CONSTRAINT ads_account_fk
    FOREIGN KEY (account_id) REFERENCES accounts (id);
ALTER TABLE clicks ADD CONSTRAINT clicks_ad_fk
    FOREIGN KEY (account_id, ad_id) REFERENCES ads (account_id, id);
```

Similarly, include the distribution column in uniqueness constraints:

```
-- Suppose we want every ad to use a unique image. Notice we can
-- enforce it only per account when we distribute by account_id
```

```
ALTER TABLE ads ADD CONSTRAINT ads_unique_image
    UNIQUE (account_id, image_url);
```

Not-null constraints can be applied to any column (distribution or not) because they require no lookups between workers.

```
ALTER TABLE ads ALTER COLUMN image_url SET NOT NULL;
```

#### Using NOT VALID Constraints

In some situations it can be useful to enforce constraints for new rows, while allowing existing non-conforming rows to remain unchanged. citus supports this feature for the `CHECK` constraints and foreign keys using the Postgres Pro `NOT VALID` constraint designation.

For example, consider an application that stores user profiles in a [reference table](#).

```
-- We are using the "text" column type here, but a real application
-- might use "citext", which is available in the
-- Postgres Pro contrib module
```

```
CREATE TABLE users ( email text PRIMARY KEY );
SELECT create_reference_table('users');
```

In the course of time imagine that a few non-addresses get into the table.

```
INSERT INTO users VALUES
    ('foo@example.com'), ('hacker12@aol.com'), ('lol');
```

We would like to validate the addresses, but Postgres Pro does not ordinarily allow us to add the `CHECK` constraint that fails for existing rows. However, it *does* allow a constraint marked `NOT VALID`:

```
ALTER TABLE users
ADD CONSTRAINT syntactic_email
CHECK (email ~
    '^[a-zA-Z0-9.!#$%&'\"'*/+=?^_`{|}~-]+@[a-zA-Z0-9](?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])?(?:
    \.[a-zA-Z0-9](?:[a-zA-Z0-9-]{0,61}[a-zA-Z0-9])?)*$'
) NOT VALID;
```

This succeeds, and new rows are protected.

```
INSERT INTO users VALUES ('fake');
```

```
/*
ERROR:  new row for relation "users_102010" violates
        check constraint "syntactic_email_102010"
DETAIL:  Failing row contains (fake).
*/
```

Later, during non-peak hours, a database administrator can attempt to fix the bad rows and re-validate the constraint.

```
-- Later, attempt to validate all rows
ALTER TABLE users
VALIDATE CONSTRAINT syntactic_email;
```

The Postgres Pro documentation has more information about `NOT VALID` and `VALIDATE CONSTRAINT` in the section about the `ALTER TABLE` command.

### Adding/Removing Indices

citux supports adding and removing [indices](#):

```
-- Adding an index

CREATE INDEX clicked_at_idx ON clicks USING BRIN (clicked_at);

-- Removing an index

DROP INDEX clicked_at_idx;
```

Adding an index takes a write lock, which can be undesirable in a multi-tenant “system-of-record”. To minimize application downtime, create the index [concurrently](#) instead. This method requires more total work than a standard index build and takes significantly longer to complete. However, since it allows normal operations to continue while the index is built, this method is useful for adding new indexes in a production environment.

```
-- Adding an index without locking table writes

CREATE INDEX CONCURRENTLY clicked_at_idx ON clicks USING BRIN (clicked_at);
```

#### J.5.7.4.1.6. Types and Functions

Creating custom SQL types and user-defined functions propagates to worker nodes. However, creating such database objects in a transaction with distributed operations involves tradeoffs.

citux parallelizes operations such as [create\\_distributed\\_table](#) across shards using multiple connections per worker. Whereas, when creating a database object, citux propagates it to worker nodes using a single connection per worker. Combining the two operations in a single transaction may cause issues, because the parallel connections will not be able to see the object that was created over a single connection but not yet committed.

Consider a transaction block that creates a type, a table, loads data, and distributes the table:

```
BEGIN;

-- Type creation over a single connection:
CREATE TYPE coordinates AS (x int, y int);
CREATE TABLE positions (object_id text primary key, position coordinates);

-- Data loading thus goes over a single connection:
SELECT create_distributed_table('positions', 'object_id');
\COPY positions FROM 'positions.csv'

COMMIT;
```

citux default behaviour prioritizes schema consistency between coordinator and worker nodes. This behavior has a downside: if object propagation happens after a parallel command in the same transaction, then the transaction can no longer be completed, as highlighted by the `ERROR` in the code block below:

```
BEGIN;
CREATE TABLE items (key text, value text);
```

```
-- Parallel data loading:
SELECT create_distributed_table('items', 'key');
\COPY items FROM 'items.csv'
CREATE TYPE coordinates AS (x int, y int);
```

ERROR: cannot run type command because there was a parallel operation on a distributed table in the transaction

If you run into this issue, there is a simple workaround: use the `citus.multi_shard_modify_mode` parameter set to `sequential` to disable per-node parallelism. Data load in the same transaction might be slower.

#### J.5.7.4.1.7. Manual Modification

Most DDL commands are auto-propagated. For any others, you can propagate the changes manually. See the [Manual Query Propagation](#) section.

#### J.5.7.4.2. Ingesting, Modifying Data (DML)

##### J.5.7.4.2.1. Inserting Data

To insert data into distributed tables, you can use the standard Postgres Pro `INSERT` command. As an example, we pick two rows randomly from the `GitHub Archive` dataset.

```
/*
CREATE TABLE github_events
(
    event_id bigint,
    event_type text,
    event_public boolean,
    repo_id bigint,
    payload jsonb,
    repo jsonb,
    actor jsonb,
    org jsonb,
    created_at timestamp
);
*/

INSERT INTO github_events VALUES (2489373118,'PublicEvent','t',24509048,'{}','{"id":
24509048, "url": "https://api.github.com/repos/SabinaS/csee6868", "name": "SabinaS/
csee6868"}','{"id": 2955009, "url": "https://api.github.com/users/SabinaS", "login":
"SabinaS", "avatar_url": "https://avatars.githubusercontent.com/u/2955009?",
"gravatar_id": ""}','NULL','2015-01-01 00:09:13');

INSERT INTO github_events VALUES (2489368389,'WatchEvent','t',28229924,'{"action":
"started"}','{"id": 28229924, "url": "https://api.github.com/repos/inf0rmer/
blanket", "name": "inf0rmer/blanket"}','{"id": 1405427, "url": "https://
api.github.com/users/tategakibunko", "login": "tategakibunko", "avatar_url": "https://
avatars.githubusercontent.com/u/1405427?", "gravatar_id": ""}','NULL','2015-01-01
00:00:24');
```

When inserting rows into distributed tables, the distribution column of the row being inserted must be specified. Based on the distribution column, citus determines the right shard to which the insert should be routed to. Then, the query is forwarded to the right shard, and the remote `INSERT` command is executed on all the replicas of that shard.

Sometimes it is convenient to put multiple `INSERT` statements together into a single `INSERT` of multiple rows. It can also be more efficient than making repeated database queries. For instance, the example from the previous section can be loaded all at once like this:

```
INSERT INTO github_events VALUES
```

```
(
  2489373118, 'PublicEvent', 't', 24509048, '{}', '{"id": 24509048, "url": "https://
api.github.com/repos/SabinaS/csee6868", "name": "SabinaS/csee6868"}', '{"id":
2955009, "url": "https://api.github.com/users/SabinaS", "login": "SabinaS",
"avatar_url": "https://avatars.githubusercontent.com/u/2955009?", "gravatar_id":
""}', NULL, '2015-01-01 00:09:13'
), (
  2489368389, 'WatchEvent', 't', 28229924, '{"action": "started"}', '{"id": 28229924,
"url": "https://api.github.com/repos/inf0rmer/blanket", "name": "inf0rmer/
blanket"}', '{"id": 1405427, "url": "https://api.github.com/users/tategakibunko",
"login": "tategakibunko", "avatar_url": "https://avatars.githubusercontent.com/
u/1405427?", "gravatar_id": ""}', NULL, '2015-01-01 00:00:24'
);
```

### Distributed Rollups

citus also supports `INSERT ... SELECT` statements, which insert rows based on the results of the `SELECT` query. This is a convenient way to fill tables and also allows [UPSERTS](#) with the `ON CONFLICT` clause, the easiest way to do [distributed rollups](#).

In citus there are three ways that inserting from the `SELECT` statement can happen:

- The first is if the source tables and the destination table are [co-located](#) and the `SELECT/INSERT` statements both include the distribution column. In this case, citus can push the `INSERT ... SELECT` statement down for parallel execution on all nodes.
- The second way of executing the `INSERT ... SELECT` statement is by repartitioning the results of the result set into chunks, and sending those chunks among workers to matching destination table shards. Each worker node can insert the values into local destination shards.

The repartitioning optimization can happen when the `SELECT` query does not require a merge step on the coordinator. It does not work with the following SQL features, which require a merge step:

- `ORDER BY`
- `LIMIT`
- `OFFSET`
- `GROUP BY` when distribution column is not part of the group key
- Window functions when partitioning by a non-distribution column in the source table(s)
- Joins between non-co-located tables (i.e. repartition joins)
- When the source and destination tables are not co-located and the repartition optimization cannot be applied, then citus uses the third way of executing `INSERT ... SELECT`. It selects the results from worker nodes and pulls the data up to the coordinator node. The coordinator redirects rows back down to the appropriate shard. Because all the data must pass through a single node, this method is not as efficient.

When in doubt about which method citus is using, use the `EXPLAIN` command, as described in the [Postgres Pro Tuning](#) section. When the target table has a very large shard count, it may be wise to disable repartitioning, see the [citus.enable\\_repartitioned\\_insert\\_select](#) configuration parameter.

### The `\copy` Command (Bulk Load)

To bulk load data from a file, you can directly use the `\copy` command.

First download our example `github_events` dataset by running:

```
wget http://examples.citusdata.com/github_archive/github_events-2015-01-01-
{0..5}.csv.gz
gzip -d github_events-2015-01-01-*.gz
```

Then, you can copy the data using `psql`. Note that this data requires the database to have UTF-8 encoding:

```
\COPY github_events FROM 'github_events-2015-01-01-0.csv' WITH (format CSV)
```

### Note

There is no notion of snapshot isolation across shards, which means that a multi-shard `SELECT` that runs concurrently with the `\copy` command might see it committed on some shards, but not on others. If the user is storing events data, he may occasionally observe small gaps in recent data. It is up to applications to deal with this if it is a problem (e.g. exclude the most recent data from queries or use some lock).

If `\copy` fails to open a connection for a shard placement, then it behaves in the same way as `INSERT`, namely to mark the placement(s) as inactive unless there are no more active placements. If any other failure occurs after connecting, the transaction is rolled back and thus no metadata changes are made.

#### J.5.7.4.3. Caching Aggregations with Rollups

Applications like event data pipelines and real-time dashboards require sub-second queries on large volumes of data. One way to make these queries fast is by calculating and saving aggregates ahead of time. This is called “rolling up” the data and it avoids the cost of processing raw data at run-time. As an extra benefit, rolling up timeseries data into hourly or daily statistics can also save space. Old data may be deleted when its full details are no longer needed and aggregates suffice.

For example, here is a distributed table for tracking page views by URL:

```
CREATE TABLE page_views (
  site_id int,
  url text,
  host_ip inet,
  view_time timestamp default now(),

  PRIMARY KEY (site_id, url)
);

SELECT create_distributed_table('page_views', 'site_id');
```

Once the table is populated with data, we can run an aggregate query to count page views per URL per day, restricting to a given site and year.

```
-- How many views per url per day on site 5?
SELECT view_time::date AS day, site_id, url, count(*) AS view_count
FROM page_views
WHERE site_id = 5 AND
      view_time >= date '2016-01-01' AND view_time < date '2017-01-01'
GROUP BY view_time::date, site_id, url;
```

The setup described above works but has two drawbacks. First, when you repeatedly execute the aggregate query, it must go over each related row and recompute the results for the entire data set. If you are using this query to render a dashboard, it is faster to save the aggregated results in a daily page views table and query that table. Second, storage costs will grow proportionally with data volumes and the length of queryable history. In practice, you may want to keep raw events for a short time period and look at historical graphs over a longer time window.

To receive those benefits, we can create the `daily_page_views` table to store the daily statistics.

```
CREATE TABLE daily_page_views (
  site_id int,
  day date,
  url text,
  view_count bigint,
```

```
PRIMARY KEY (site_id, day, url)
);
```

```
SELECT create_distributed_table('daily_page_views', 'site_id');
```

In this example, we distributed both `page_views` and `daily_page_views` on the `site_id` column. This ensures that data corresponding to a particular site will be [co-located](#) on the same node. Keeping the rows of the two tables together on each node minimizes network traffic between nodes and enables highly parallel execution.

Once we create this new distributed table, we can then run `INSERT INTO ... SELECT` to roll up raw page views into the aggregated table. In the following, we aggregate page views each day. citus users often wait for a certain time period after the end of day to run a query like this, to accommodate late arriving data.

```
-- Roll up yesterday's data
INSERT INTO daily_page_views (day, site_id, url, view_count)
  SELECT view_time::date AS day, site_id, url, count(*) AS view_count
  FROM page_views
  WHERE view_time >= date '2017-01-01' AND view_time < date '2017-01-02'
  GROUP BY view_time::date, site_id, url;

-- Now the results are available right out of the table
SELECT day, site_id, url, view_count
  FROM daily_page_views
  WHERE site_id = 5 AND
    day >= date '2016-01-01' AND day < date '2017-01-01';
```

The rollup query above aggregates data from the previous day and inserts it into the `daily_page_views` table. Running the query once each day means that no rollup tables rows need to be updated, because the new day's data does not affect previous rows.

The situation changes when dealing with late arriving data, or running the rollup query more than once per day. If any new rows match days already in the rollup table, the matching counts should increase. Postgres Pro can handle this situation with `ON CONFLICT`, which is its technique for doing [UPSERTS](#). Here is an example.

```
-- Roll up from a given date onward,
-- updating daily page views when necessary
INSERT INTO daily_page_views (day, site_id, url, view_count)
  SELECT view_time::date AS day, site_id, url, count(*) AS view_count
  FROM page_views
  WHERE view_time >= date '2017-01-01'
  GROUP BY view_time::date, site_id, url
  ON CONFLICT (day, url, site_id) DO UPDATE SET
    view_count = daily_page_views.view_count + EXCLUDED.view_count;
```

#### J.5.7.4.3.1. Updates and Deletion

You can update or delete rows from your distributed tables using the standard Postgres Pro [UPDATE](#) and [DELETE](#) commands.

```
DELETE FROM github_events
WHERE repo_id IN (24509048, 24509049);

UPDATE github_events
SET event_public = TRUE
WHERE (org->>'id')::int = 5430905;
```

When the `UPDATE/DELETE` operations affect multiple shards as in the above example, citus defaults to using a one-phase commit protocol. For greater safety you can enable two-phase commits by setting the `citus.multi_shard_commit_protocol` configuration parameter:

```
SET citus.multi_shard_commit_protocol = '2pc';
```

If an `UPDATE` or `DELETE` operation affects only a single shard, then it runs within a single worker node. In this case enabling 2PC is unnecessary. This often happens when updates or deletes filter by a table's distribution column:

```
-- Since github_events is distributed by repo_id,  
-- this will execute in a single worker node
```

```
DELETE FROM github_events  
WHERE repo_id = 206084;
```

Furthermore, when dealing with a single shard, citus supports `SELECT ... FOR UPDATE`. This is a technique sometimes used by object-relational mappers (ORMs) to safely:

- Load rows
- Make a calculation in application code
- Update the rows based on calculation

Selecting the rows for update puts a write lock on them to prevent other processes from causing the “lost update” anomaly.

```
BEGIN;  
  
-- Select events for a repo, but  
-- lock them for writing  
SELECT *  
FROM github_events  
WHERE repo_id = 206084  
FOR UPDATE;  
  
-- Calculate a desired value event_public using  
-- application logic that uses those rows  
  
-- Now make the update  
UPDATE github_events  
SET event_public = :our_new_value  
WHERE repo_id = 206084;  
  
COMMIT;
```

This feature is supported for hash distributed and reference tables only.

#### **J.5.7.4.3.2. Maximizing Write Performance**

Both `INSERT` and `UPDATE/DELETE` statements can be scaled up to around 50,000 queries per second on large machines. However, to achieve this rate, you will need to use many parallel, long-lived connections and consider how to deal with locking. For more information, you can consult the [Scaling Out Data Ingestion](#) section.

#### **J.5.7.4.4. Querying Distributed Tables (SQL)**

As discussed in the previous sections, citus extends the latest Postgres Pro for distributed execution. This means that you can use standard Postgres Pro `SELECT` queries on the citus coordinator. The extension will then parallelize the `SELECT` queries involving complex selections, groupings and orderings, and `JOINS` to speed up the query performance. At a high level, citus partitions the `SELECT` query into smaller query fragments, assigns these query fragments to workers, oversees their execution, merges their results (and orders them if needed), and returns the final result to the user.

In the following sections, we discuss the different types of queries you can run using citus.

#### J.5.7.4.4.1. Aggregate Functions

citus supports and parallelizes most aggregate functions supported by Postgres Pro, including custom user-defined aggregates. Aggregates execute using one of three methods, in this order of preference:

- When the aggregate is grouped by a distribution column of a table, citus can push down execution of the entire query to each worker. All aggregates are supported in this situation and execute in parallel on the worker nodes. (Any custom aggregates being used must be installed on the workers.)
- When the aggregate is *not* grouped by a distribution column, citus can still optimize on a case-by-case basis. citus has internal rules for certain aggregates like `sum()`, `avg()`, and `count(distinct)` that allow it to rewrite queries for *partial aggregation* on workers. For instance, to calculate an average, citus obtains a sum and a count from each worker, and then the coordinator node computes the final average.

Full list of the special-case aggregates:

```
avg, min, max, sum, count, array_agg, jsonb_agg, jsonb_object_agg, json_agg, json_object_agg, bit_and, bit_or, bool_and, bool_or, every, hll_add_agg, hll_union_agg, topn_add_agg, topn_union_agg, any_value, tdigest(double precision, int), tdigest_percentile(double precision, int, double precision), tdigest_percentile(double precision, int, double precision[]), tdigest_percentile(tdigest, double precision), tdigest_percentile(tdigest, double precision[]), tdigest_percentile_of(double precision, int, double precision), tdigest_percentile_of(double precision, int, double precision[]), tdigest_percentile_of(tdigest, double precision), tdigest_percentile_of(tdigest, double precision[])
```

- Last resort: pull all rows from the workers and perform the aggregation on the coordinator node. When the aggregate is not grouped on a distribution column, and is not one of the predefined special cases, then citus falls back to this approach. It causes network overhead and can exhaust the coordinator resources if the data set to be aggregated is too large. (It is possible to disable this fallback, see below.)

Beware that small changes in a query can change execution modes causing potentially surprising inefficiency. For example, `sum(x)` grouped by a non-distribution column could use distributed execution, while `sum(distinct x)` has to pull up the entire set of input records to the coordinator.

All it takes is one column to hurt the execution of a whole query. In the example below, if `sum(distinct value2)` has to be grouped on the coordinator, then so will `sum(value1)` even if the latter was fine on its own.

```
SELECT sum(value1), sum(distinct value2) FROM distributed_table;
```

To avoid accidentally pulling data to the coordinator, you can set the `citus.coordinator_aggregation_strategy` parameter:

```
SET citus.coordinator_aggregation_strategy TO 'disabled';
```

Note that disabling the coordinator aggregation strategy will prevent “type three” aggregate queries from working at all.

#### The `count(distinct)` Aggregates

citus supports `count(distinct)` aggregates in several ways. If the `count(distinct)` aggregate is on the distribution column, citus can directly push down the query to the workers. If not, citus runs `SELECT distinct` statements on each worker and returns the list to the coordinator where it obtains the final count.

Note that transferring this data becomes slower when workers have a greater number of distinct items. This is especially true for queries containing multiple `count(distinct)` aggregates, e.g.:

```
-- Multiple distinct counts in one query tend to be slow
SELECT count(distinct a), count(distinct b), count(distinct c)
```

```
FROM table_abc;
```

For these kind of queries, the resulting `SELECT distinct` statements on the workers essentially produce a cross-product of rows to be transferred to the coordinator.

For increased performance you can choose to make an approximate count instead. Follow the steps below:

1. Download and install the hll extension on all Postgres Pro instances (the coordinator and all the workers).

You can visit the hll [GitHub repository](#) for specifics on obtaining the extension.

2. Create the hll extension on all the Postgres Pro instances by simply running the below command from the coordinator:

```
CREATE EXTENSION hll;
```

3. Enable `count(distinct)` approximations by setting the [citus.count\\_distinct\\_error\\_rate](#) configuration parameter. Lower values for this configuration setting are expected to give more accurate results but take more time for computation. We recommend setting this to `0.005`.

```
SET citus.count_distinct_error_rate TO 0.005;
```

After this step, `count(distinct)` aggregates automatically switch to using hll with no changes necessary to your queries. You should be able to run approximate `count(distinct)` queries on any column of the table.

**HyperLogLog Column.** Certain users already store their data as hll columns. In such cases, they can dynamically roll up those data by calling the `hll_union_agg(hll_column)` function.

### Estimating Top N Items

Calculating the first  $n$  elements in a set by applying `count`, `sort`, and `limit` is simple. However, as data sizes increase, this method becomes slow and resource intensive. It is more efficient to use an approximation.

The open source [topn](#) extension for Postgres Pro enables fast approximate results to “top-n” queries. The extension materializes the top values into a `json` data type. The `topn` extension can incrementally update these top values or merge them on-demand across different time intervals.

Before seeing a realistic example of `topn`, let's see how some of its primitive operations work. First `topn_add` updates a JSON object with counts of how many times a key has been seen:

```
-- Starting from nothing, record that we saw an "a"
SELECT topn_add('{}', 'a');
-- => {"a": 1}
```

```
-- Record the sighting of another "a"
SELECT topn_add(topn_add('{}', 'a'), 'a');
-- => {"a": 2}
```

The extension also provides aggregations to scan multiple values:

```
-- For normal_rand
CREATE EXTENSION tablefunc;

-- Count values from a normal distribution
SELECT topn_add_agg(floor(abs(i))::text)
  FROM normal_rand(1000, 5, 0.7) i;
-- => {"2": 1, "3": 74, "4": 420, "5": 425, "6": 77, "7": 3}
```

If the number of distinct values crosses a threshold, the aggregation drops information for those seen least frequently. This keeps space usage under control. The threshold can be controlled by the `topn.number_of_counters` configuration parameter. Its default value is `1000`.

Now onto a more realistic example of how topn works in practice. Let's ingest Amazon product reviews from the year 2000 and use topn to query it quickly. First download the dataset:

```
curl -L https://examples.citusdata.com/customer_reviews_2000.csv.gz | \
gunzip > reviews.csv
```

Next, ingest it into a distributed table:

```
CREATE TABLE customer_reviews
(
    customer_id TEXT,
    review_date DATE,
    review_rating INTEGER,
    review_votes INTEGER,
    review_helpful_votes INTEGER,
    product_id CHAR(10),
    product_title TEXT,
    product_sales_rank BIGINT,
    product_group TEXT,
    product_category TEXT,
    product_subcategory TEXT,
    similar_product_ids CHAR(10)[]
);

SELECT create_distributed_table('customer_reviews', 'product_id');

\COPY customer_reviews FROM 'reviews.csv' WITH CSV
```

Next we will add the extension, create a destination table to store the JSON data generated by topn, and apply the topn\_add\_agg function we saw previously.

```
-- Run below command from coordinator, it will be propagated to the worker nodes as
well
CREATE EXTENSION topn;

-- A table to materialize the daily aggregate
CREATE TABLE reviews_by_day
(
    review_date date unique,
    agg_data jsonb
);

SELECT create_reference_table('reviews_by_day');

-- Materialize how many reviews each product got per day per customer
INSERT INTO reviews_by_day
SELECT review_date, topn_add_agg(product_id)
FROM customer_reviews
GROUP BY review_date;
```

Now, rather than writing a complex window function on `customer_reviews`, we can simply apply topn to `reviews_by_day`. For instance, the following query finds the most frequently reviewed product for each of the first five days:

```
SELECT review_date, (topn(agg_data, 1)).*
FROM reviews_by_day
ORDER BY review_date
LIMIT 5;
```

| review_date | item | frequency |
|-------------|------|-----------|
|             |      |           |

|            |            |    |
|------------|------------|----|
| 2000-01-01 | 0939173344 | 12 |
| 2000-01-02 | B000050XY8 | 11 |
| 2000-01-03 | 0375404368 | 12 |
| 2000-01-04 | 0375408738 | 14 |
| 2000-01-05 | B00000J7J4 | 17 |

The JSON fields created by `topn` can be merged with `topn_union` and `topn_union_agg`. We can use the latter to merge the data for the entire first month and list the five most reviewed products during that period.

```
SELECT (topn(topn_union_agg(agg_data), 5)).*
FROM reviews_by_day
WHERE review_date >= '2000-01-01' AND review_date < '2000-02-01'
ORDER BY 2 DESC;
```

| item       | frequency |
|------------|-----------|
| 0375404368 | 217       |
| 0345417623 | 217       |
| 0375404376 | 217       |
| 0375408738 | 217       |
| 043936213X | 204       |

For more details and examples, see the [topn readme file](#).

#### Percentile Calculations

Finding an exact percentile over a large number of rows can be prohibitively expensive, because all rows must be transferred to the coordinator for final sorting and processing. Finding an approximation, on the other hand, can be done in parallel on worker nodes using a so-called *sketch algorithm*. The coordinator node then combines compressed summaries into the final result rather than reading through the full rows.

A popular sketch algorithm for percentiles uses a compressed data structure called *t-digest*, and is available for Postgres Pro in the [tdigest extension](#). `citus` has integrated support for this extension.

Here is how to use `tdigest` in `citus`:

1. Download and install the `tdigest` extension on all Postgres Pro nodes (the coordinator and all the workers). The [tdigest extension GitHub repository](#) has installation instructions.
2. Create the `tdigest` extension within the database. Run the following command on the coordinator:

```
CREATE EXTENSION tdigest;
```

The coordinator will propagate the command to the workers as well.

When any of the aggregates defined in the extension are used in queries, `citus` will rewrite the queries to push down partial `tdigest` computation to the workers where applicable.

`tdigest` accuracy can be controlled with the `compression` argument passed into aggregates. The trade-off is accuracy vs the amount of data shared between workers and the coordinator. For a full explanation of how to use the aggregates in `tdigest`, have a look at the documentation of the extension.

#### J.5.7.4.4.2. Limit Pushdown

`citus` also pushes down the limit clauses to the shards on the workers wherever possible to minimize the amount of data transferred across network.

However, in some cases, `SELECT` queries with `LIMIT` clauses may need to fetch all rows from each shard to generate exact results. For example, if the query requires ordering by the aggregate column, it would

need results of that column from all shards to determine the final aggregate value. This reduces performance of the `LIMIT` clause due to high volume of network data transfer. In such cases, and where an approximation would produce meaningful results, citus provides an option for network efficient approximate `LIMIT` clauses.

`LIMIT` approximations are disabled by default and can be enabled by setting the [citus.limit\\_clause\\_row\\_fetch\\_count](#) configuration parameter. On the basis of this configuration value, citus will limit the number of rows returned by each task for aggregation on the coordinator. Due to this limit, the final results may be approximate. Increasing this limit will increase the accuracy of the final results, while still providing an upper bound on the number of rows pulled from the workers.

```
SET citus.limit_clause_row_fetch_count TO 10000;
```

#### J.5.7.4.4.3. Views on Distributed Tables

citus supports all views on distributed tables. To learn more about syntax and features of views, see the section about the [CREATE VIEW](#) command.

Note that some views cause a less efficient query plan than others. For more information about detecting and improving poor view performance, see the [Subquery/CTE Network Overhead](#) section. (Views are treated inside the extension as subqueries.)

citus supports materialized views as well and stores them as local tables on the coordinator node.

#### J.5.7.4.4.4. Joins

citus supports equi-joins between any number of tables irrespective of their size and distribution method. The query planner chooses the optimal join method and join order based on how tables are distributed. It evaluates several possible join orders and creates a join plan which requires minimum data to be transferred across network.

##### Co-Located Joins

When two tables are [co-located](#) then they can be joined efficiently on their common distribution columns. A co-located join is the most efficient way to join two large distributed tables.

Internally, the citus coordinator knows which shards of the co-located tables might match with shards of the other table by looking at the distribution column metadata. This allows citus to prune away shard pairs, which cannot produce matching join keys. The joins between remaining shard pairs are executed in parallel on the workers and then the results are returned to the coordinator.

### Note

Be sure that the tables are distributed into the same number of shards and that the distribution columns of each table have exactly matching types. Attempting to join on columns of slightly different types such as `int` and `bigint` can cause problems.

##### Reference Table Joins

[Reference tables](#) can be used as “dimension” tables to join efficiently with large “fact” tables. Because reference tables are replicated in full across all worker nodes, a reference join can be decomposed into local joins on each worker and performed in parallel. A reference join is like a more flexible version of a co-located join because reference tables are not distributed on any particular column and are free to join on any of their columns.

Reference tables can also join with tables local to the coordinator node.

##### Repartition Joins

In some cases, you may need to join two tables on columns other than the distribution column. For such cases, citus also allows joining on non-distribution key columns by dynamically repartitioning the tables for the query.

In such cases the table(s) to be partitioned are determined by the query optimizer on the basis of the distribution columns, join keys and sizes of the tables. With repartitioned tables, it can be ensured that only relevant shard pairs are joined with each other reducing the amount of data transferred across network drastically.

In general, co-located joins are more efficient than repartition joins as repartition joins require shuffling of data. So, you should try to distribute your tables by the common join keys whenever possible.

#### J.5.7.4.5. Query Processing

A citus cluster consists of a coordinator instance and multiple worker instances. The data is sharded on the workers while the coordinator stores metadata about these shards. All queries issued to the cluster are executed via the coordinator. The coordinator partitions the query into smaller query fragments where each query fragment can be run independently on a shard. The coordinator then assigns the query fragments to workers, oversees their execution, merges their results, and returns the final result to the user. The query processing architecture can be described in brief by the [diagram](#) below.

**Figure J.16. Query Processing Architecture**

citus query processing pipeline involves the two components:

- Distributed query planner and executor
- Postgres Pro planner and executor

We discuss them in greater detail in the subsequent sections.

#### **J.5.7.4.5.1. Distributed Query Planner**

citius distributed query planner takes in a SQL query and plans it for distributed execution.

For `SELECT` queries, the planner first creates a plan tree of the input query and transforms it into its commutative and associative form so it can be parallelized. It also applies several optimizations to ensure that the queries are executed in a scalable manner, and that network I/O is minimized.

Next, the planner breaks the query into two parts: the coordinator query, which runs on the coordinator, and the worker query fragments, which run on individual shards on the workers. The planner then assigns these query fragments to the workers such that all their resources are used efficiently. After this step, the distributed query plan is passed on to the distributed executor for execution.

The planning process for key-value lookups on the distribution column or modification queries is slightly different as they hit exactly one shard. Once the planner receives an incoming query, it needs to decide the correct shard to which the query should be routed. To do this, it extracts the distribution column in the incoming row and looks up the metadata to determine the right shard for the query. Then, the planner rewrites the SQL of that command to reference the shard table instead of the original table. This re-written plan is then passed to the distributed executor.

#### **J.5.7.4.5.2. Distributed Query Executor**

citius distributed executor runs distributed query plans and handles failures. The executor is well suited for getting fast responses to queries involving filters, aggregations, and co-located joins, as well as running single-tenant queries with full SQL coverage. It opens one connection per shard to the workers as needed and sends all fragment queries to them. It then fetches the results from each fragment query, merges them, and gives the final results back to the user.

#### **Subquery/CTE Push-Pull Execution**

If necessary citius can gather results from subqueries and CTEs into the coordinator node and then push them back across workers for use by an outer query. This allows citius to support a greater variety of SQL constructs.

For example, having subqueries in the `WHERE` clause sometimes cannot execute inline at the same time as the main query, but must be done separately. Suppose a web analytics application maintains a `page_views` table partitioned by `page_id`. To query the number of visitor hosts on the top twenty most visited pages, we can use a subquery to find the list of pages, then an outer query to count the hosts.

```
SELECT page_id, count(distinct host_ip)
FROM page_views
WHERE page_id IN (
    SELECT page_id
    FROM page_views
    GROUP BY page_id
    ORDER BY count(*) DESC
    LIMIT 20
)
GROUP BY page_id;
```

The executor would like to run a fragment of this query against each shard by `page_id`, counting distinct `host_ips`, and combining the results on the coordinator. However, the `LIMIT` in the subquery means the subquery cannot be executed as part of the fragment. By recursively planning the query citius can run the subquery separately, push the results to all workers, run the main fragment query, and pull the results back to the coordinator. The “push-pull” design supports subqueries like the one above.

Let's see this in action by reviewing the [EXPLAIN](#) output for this query. It is fairly involved:

```
GroupAggregate (cost=0.00..0.00 rows=0 width=0)
```

```

Group Key: remote_scan.page_id
-> Sort (cost=0.00..0.00 rows=0 width=0)
    Sort Key: remote_scan.page_id
-> Custom Scan (Citrus Adaptive) (cost=0.00..0.00 rows=0 width=0)
    -> Distributed Subplan 6_1
        -> Limit (cost=0.00..0.00 rows=0 width=0)
            -> Sort (cost=0.00..0.00 rows=0 width=0)
                Sort Key:
COALESCE((pg_catalog.sum((COALESCE((pg_catalog.sum(remote_scan.worker_column_2))::bigint,
'0'::bigint))))::bigint, '0'::bigint) DESC
            -> HashAggregate (cost=0.00..0.00 rows=0 width=0)
                Group Key: remote_scan.page_id
                -> Custom Scan (Citrus Adaptive) (cost=0.00..0.00 rows=0 width=0)
                    Task Count: 32
                    Tasks Shown: One of 32
                    -> Task
                        Node: host=localhost port=9701 dbname=postgres
                        -> HashAggregate (cost=54.70..56.70 rows=200 width=12)
                            Group Key: page_id
                            -> Seq Scan on page_views_102008 page_views (cost=0.00..43.47
rows=2247 width=4)
                                Task Count: 32
                                Tasks Shown: One of 32
                                -> Task
                                    Node: host=localhost port=9701 dbname=postgres
                                    -> HashAggregate (cost=84.50..86.75 rows=225 width=36)
  Group Key: page_views.page_id, page_views.host_ip
  -> Hash Join (cost=17.00..78.88 rows=1124 width=36)
  Hash Cond: (page_views.page_id = intermediate_result.page_id)
  -> Seq Scan on page_views_102008 page_views (cost=0.00..43.47 rows=2247
width=36)
  -> Hash (cost=14.50..14.50 rows=200 width=4)
  -> HashAggregate (cost=12.50..14.50 rows=200 width=4)
  Group Key: intermediate_result.page_id
  -> Function Scan on read_intermediate_result intermediate_result
(cost=0.00..10.00 rows=1000 width=4)

```

Let's break it apart and examine each piece.

```

GroupAggregate (cost=0.00..0.00 rows=0 width=0)
  Group Key: remote_scan.page_id
  -> Sort (cost=0.00..0.00 rows=0 width=0)
      Sort Key: remote_scan.page_id

```

The root of the tree is what the coordinator node does with the results from the workers. In this case, it is grouping them, and GroupAggregate requires they be sorted first.

```

-> Custom Scan (Citrus Adaptive) (cost=0.00..0.00 rows=0 width=0)
    -> Distributed Subplan 6_1
    .

```

The custom scan has two large sub-trees, starting with a “distributed subplan”.

```

-> Limit (cost=0.00..0.00 rows=0 width=0)
    -> Sort (cost=0.00..0.00 rows=0 width=0)
        Sort Key:
COALESCE((pg_catalog.sum((COALESCE((pg_catalog.sum(remote_scan.worker_column_2))::bigint,
'0'::bigint))))::bigint, '0'::bigint) DESC
    -> HashAggregate (cost=0.00..0.00 rows=0 width=0)
        Group Key: remote_scan.page_id

```

```
-> Custom Scan (Citus Adaptive) (cost=0.00..0.00 rows=0 width=0)
    Task Count: 32
    Tasks Shown: One of 32
    -> Task
        Node: host=localhost port=9701 dbname=postgres
        -> HashAggregate (cost=54.70..56.70 rows=200 width=12)
            Group Key: page_id
            -> Seq Scan on page_views_102008 page_views (cost=0.00..43.47 rows=2247
width=4)
.
```

Worker nodes run the above for each of the thirty-two shards (citus is choosing one representative for display). We can recognize all the pieces of the `IN (...)` subquery: the sorting, grouping and limiting. When all workers have completed this query, they send their output back to the coordinator which puts it together as “intermediate results”.

```
Task Count: 32
Tasks Shown: One of 32
-> Task
    Node: host=localhost port=9701 dbname=postgres
    -> HashAggregate (cost=84.50..86.75 rows=225 width=36)
        Group Key: page_views.page_id, page_views.host_ip
        -> Hash Join (cost=17.00..78.88 rows=1124 width=36)
            Hash Cond: (page_views.page_id = intermediate_result.page_id)
.
```

The citus extension starts another executor job in this second subtree. It is going to count distinct hosts in `page_views`. It uses a `JOIN` to connect with the intermediate results. The intermediate results will help it restrict to the top twenty pages.

```
-> Seq Scan on page_views_102008 page_views (cost=0.00..43.47 rows=2247 width=36)
-> Hash (cost=14.50..14.50 rows=200 width=4)
    -> HashAggregate (cost=12.50..14.50 rows=200 width=4)
        Group Key: intermediate_result.page_id
        -> Function Scan on read_intermediate_result intermediate_result
(cost=0.00..10.00 rows=1000 width=4)
.
```

The worker internally retrieves intermediate results using the `read_intermediate_result` function, which loads data from a file that was copied in from the coordinator node.

This example showed how citus executed the query in multiple steps with a distributed subplan and how you can use `EXPLAIN` to learn about distributed query execution.

#### J.5.7.4.5.3. Postgres Pro Planner and Executor

Once the distributed executor sends the query fragments to the workers, they are processed like regular Postgres Pro queries. The Postgres Pro planner on that worker chooses the most optimal plan for executing that query locally on the corresponding shard table. The Postgres Pro executor then runs that query and returns the query results back to the distributed executor. Learn more about the Postgres Pro [planner](#) and [executor](#). Finally, the distributed executor passes the results to the coordinator for final aggregation.

#### J.5.7.4.6. Manual Query Propagation

When the user issues a query, the citus coordinator partitions it into smaller query fragments where each query fragment can be run independently on a worker shard. This allows citus to distribute each query across the cluster.

However, the way queries are partitioned into fragments (and which queries are propagated at all) varies by the type of query. In some advanced situations it is useful to manually control this behavior. citus provides utility functions to propagate SQL to workers, shards, or co-located placements.

Manual query propagation bypasses coordinator logic, locking, and any other consistency checks. These functions are available as a last resort to allow statements which citus otherwise does not run natively. Use them carefully to avoid data inconsistency and deadlocks.

#### J.5.7.4.6.1. Running on All Workers

The least granular level of execution is broadcasting a statement for execution on all workers. This is useful for viewing properties of entire worker databases.

```
-- List the work_mem setting of each worker database
SELECT run_command_on_workers($cmd$ SHOW work_mem; $cmd$);
```

To run on all nodes, both workers and the coordinator, use the `run_command_on_all_nodes` function.

### Note

This command should not be used to create database objects on the workers, as doing so will make it harder to add worker nodes in an automated fashion.

### Note

The `run_command_on_workers` function and other manual propagation commands in this section can run only queries that return a single column and single row.

#### J.5.7.4.6.2. Running on All Shards

The next level of granularity is running a command across all shards of a particular distributed table. It can be useful, for instance, in reading the properties of a table directly on workers. Queries run locally on a worker node have full access to metadata such as table statistics.

The `run_command_on_shards` function applies an SQL command to each shard, where the shard name is provided for interpolation in the command. Here is an example of estimating the row count for a distributed table by using the `pg_class` table on each worker to estimate the number of rows for each shard. Notice the `%s`, which will be replaced with each shard name.

```
-- Get the estimated row count for a distributed table by summing the
-- estimated counts of rows for each shard
SELECT sum(result::bigint) AS estimated_count
FROM run_command_on_shards(
    'my_distributed_table',
    $cmd$
    SELECT reltuples
    FROM pg_class c
    JOIN pg_catalog.pg_namespace n on n.oid=c.relnamespace
    WHERE (n.nspname || '.' || relname)::regclass = '%s'::regclass
    AND n.nspname NOT IN ('citus', 'pg_toast', 'pg_catalog')
    $cmd$
);
```

A useful companion to `run_command_on_shards` is the `run_command_on_collocated_placements` function. It interpolates the names of two placements of `co-located` distributed tables into a query. The placement pairs are always chosen to be local to the same worker where full SQL coverage is available. Thus we can use advanced SQL features like triggers to relate the tables:

```
-- Suppose we have two distributed tables
CREATE TABLE little_vals (key int, val int);
CREATE TABLE big_vals (key int, val int);
SELECT create_distributed_table('little_vals', 'key');
SELECT create_distributed_table('big_vals', 'key');
```

```
-- We want to synchronize them so that every time little_vals
-- are created, big_vals appear with double the value
--
-- First we make a trigger function, which will
-- take the destination table placement as an argument
CREATE OR REPLACE FUNCTION embiggen() RETURNS TRIGGER AS $$
BEGIN
    IF (TG_OP = 'INSERT') THEN
        EXECUTE format(
            'INSERT INTO %s (key, val) SELECT ($1).key, ($1).val*2;',
            TG_ARGV[0]
        ) USING NEW;
    END IF;
    RETURN NULL;
END;
$$ LANGUAGE plpgsql;

-- Next we relate the co-located tables by the trigger function
-- on each co-located placement
SELECT run_command_on_collocated_placements(
    'little_vals',
    'big_vals',
    $cmd$
    CREATE TRIGGER after_insert AFTER INSERT ON %s
    FOR EACH ROW EXECUTE PROCEDURE embiggen(%L)
    $cmd$
);
```

#### J.5.7.4.6.3. Limitations

- There are no safeguards against deadlock for multi-statement transactions.
- There are no safeguards against mid-query failures and resulting inconsistencies.
- Query results are cached in memory; these functions cannot deal with very big result sets.
- The functions error out early if they cannot connect to a node.

#### J.5.7.4.7. SQL Support and Workarounds

As Citus provides distributed functionality by extending Postgres Pro, it is compatible with Postgres Pro constructs. This means that users can use the tools and features that come with the rich and extensible Postgres Pro ecosystem for distributed tables created with Citus.

Citus has 100% SQL coverage for any queries it is able to execute on a single worker node. These kind of queries are common in [multi-tenant applications](#) when accessing information about a single tenant.

Even cross-node queries (used for parallel computations) support most SQL features. However, some SQL features are not supported for queries, which combine information from multiple nodes.

#### J.5.7.4.7.1. Limitations

##### General

These limitations apply to all models of operation:

- The [rule system](#) is not supported.
- [Subqueries within INSERT queries](#) are not supported.
- Distributing multi-level partitioned tables is not supported.
- Functions used in UPDATE queries on distributed tables must not be `VOLATILE`.
- `STABLE` functions used in UPDATE queries cannot be called with column references.

- Modifying views when the query contains citus tables is not supported.

citus encodes the node identifier in the sequence generated on every node, this allows every individual node to take inserts directly without having the sequence overlap. This method however does not work for sequences that are smaller than `bigint`, which may result in inserts on worker nodes failing, in that case you need to drop the column and add a `bigint` based one, or route the inserts via the coordinator.

#### Cross-Node SQL Queries

- `SELECT ... FOR UPDATE` work in single-shard queries only.
- `TABLESAMPLE` work in single-shard queries only.
- Correlated subqueries are supported only when the correlation is on the [distribution column](#).
- Outer joins between distributed tables are only supported on the [distribution column](#).
- [Recursive CTEs](#) work in single-shard queries only.
- [Grouping sets](#) work in single-shard queries only.
- Only regular, foreign or partitioned tables can be distributed.
- The SQL `MERGE` command is supported in the following combinations of [table types](#):

| Target      | Source      | Support | Comments                                 |
|-------------|-------------|---------|------------------------------------------|
| Local       | Local       | Yes     |                                          |
| Local       | Reference   | Yes     |                                          |
| Local       | Distributed | No      | Feature in development                   |
| Distributed | Local       | Yes     |                                          |
| Distributed | Distributed | Yes     | Including non co-located tables          |
| Distributed | Reference   | Yes     |                                          |
| Reference   | N/A         | No      | Reference table as target is not allowed |

For a detailed reference of the Postgres Pro SQL command dialect (which can be used as is by citus users), you can see the [SQL Commands](#) section.

#### Schema-Based Sharding SQL Compatibility

When using [schema-based sharding](#) the following features are not available:

- Foreign keys across distributed schemas are not supported.
- Joins across distributed schemas are subject to [cross-node SQL queries](#) limitations.
- Creating a distributed schema and tables in a single SQL statement is not supported.

#### J.5.7.4.7.2. Workarounds

Before attempting workarounds consider whether citus is appropriate for your situation. The citus extension works well for real-time analytics and multi-tenant [use cases](#).

citus supports all SQL statements in the multi-tenant use case. Even in the real-time analytics use cases, with queries that span across nodes, citus supports the majority of statements. The few types of unsupported queries are listed in the [Are there any Postgres Pro features not supported by citus?](#) section. Many of the unsupported features have workarounds; below are a number of the most useful.

#### Work Around Limitations Using CTEs

When a SQL query is unsupported, one way to work around it is using [CTEs](#), which use what we call pull-push execution.

```
SELECT * FROM dist WHERE EXISTS (SELECT 1 FROM local WHERE local.a = dist.a);
```

```
/*
ERROR:  direct joins between distributed and local tables are not supported
HINT:   Use CTEs or subqueries to select from local tables and use them in joins
*/
```

To work around this limitation, you can turn the query into a router query by wrapping the distributed part in a CTE.

```
WITH cte AS (SELECT * FROM dist)
SELECT * FROM cte WHERE EXISTS (SELECT 1 FROM local WHERE local.a = cte.a);
```

Remember that the coordinator will send the results of the CTE to all workers which require it for processing. Thus it is best to either add the most specific filters and limits to the inner query as possible, or else aggregate the table. That reduces the network overhead which such a query can cause. More about this in the [Subquery/CTE Network Overhead](#) section.

### Temp Tables: the Workaround of Last Resort

There are still a few queries that are [unsupported](#) even with the use of push-pull execution via subqueries. One of them is using [grouping sets](#) on a distributed table.

In our [real-time analytics tutorial](#) we created a table called `github_events`, distributed by the column `user_id`. Let's query it and find the earliest events for a preselected set of repos, grouped by combinations of event type and event publicity. A convenient way to do this is with grouping sets. However, as mentioned, this feature is not yet supported in distributed queries:

```
-- This will not work

SELECT repo_id, event_type, event_public,
       grouping(event_type, event_public),
       min(created_at)
FROM   github_events
WHERE  repo_id IN (8514, 15435, 19438, 21692)
GROUP BY repo_id, ROLLUP(event_type, event_public);

ERROR:  could not run distributed query with GROUPING
HINT:   Consider using an equality filter on the distributed table's partition column.
```

There is a trick, though. We can pull the relevant information to the coordinator as a temporary table:

```
-- Grab the data, minus the aggregate, into a local table

CREATE TEMP TABLE results AS (
  SELECT repo_id, event_type, event_public, created_at
  FROM   github_events
  WHERE  repo_id IN (8514, 15435, 19438, 21692)
);

-- Now run the aggregate locally

SELECT repo_id, event_type, event_public,
       grouping(event_type, event_public),
       min(created_at)
FROM   results
GROUP BY repo_id, ROLLUP(event_type, event_public);
```

| repo_id | event_type        | event_public | grouping | min                 |
|---------|-------------------|--------------|----------|---------------------|
| 8514    | PullRequestEvent  | t            | 0        | 2016-12-01 05:32:54 |
| 8514    | IssueCommentEvent | t            | 0        | 2016-12-01 05:32:57 |
| 19438   | IssueCommentEvent | t            | 0        | 2016-12-01 05:48:56 |
| 21692   | WatchEvent        | t            | 0        | 2016-12-01 06:01:23 |

|       |  |                   |  |   |  |   |  |                     |
|-------|--|-------------------|--|---|--|---|--|---------------------|
| 15435 |  | WatchEvent        |  | t |  | 0 |  | 2016-12-01 05:40:24 |
| 21692 |  | WatchEvent        |  |   |  | 1 |  | 2016-12-01 06:01:23 |
| 15435 |  | WatchEvent        |  |   |  | 1 |  | 2016-12-01 05:40:24 |
| 8514  |  | PullRequestEvent  |  |   |  | 1 |  | 2016-12-01 05:32:54 |
| 8514  |  | IssueCommentEvent |  |   |  | 1 |  | 2016-12-01 05:32:57 |
| 19438 |  | IssueCommentEvent |  |   |  | 1 |  | 2016-12-01 05:48:56 |
| 15435 |  |                   |  |   |  | 3 |  | 2016-12-01 05:40:24 |
| 21692 |  |                   |  |   |  | 3 |  | 2016-12-01 06:01:23 |
| 19438 |  |                   |  |   |  | 3 |  | 2016-12-01 05:48:56 |
| 8514  |  |                   |  |   |  | 3 |  | 2016-12-01 05:32:54 |

Creating a temporary table on the coordinator is a last resort. It is limited by the disk size and CPU of the node.

### Subqueries Within INSERT Queries

Try rewriting your queries with `INSERT INTO ... SELECT` syntax.

The following SQL:

```
INSERT INTO a.widgets (map_id, widget_name)
VALUES (
    (SELECT mt.map_id FROM a.map_tags mt WHERE mt.map_license = '12345'),
    'Test'
);
```

Would become:

```
INSERT INTO a.widgets (map_id, widget_name)
SELECT mt.map_id, 'Test'
FROM a.map_tags mt
WHERE mt.map_license = '12345';
```

## J.5.7.5. citus API

### J.5.7.5.1. citus Utility Functions

This section contains reference information for the user defined functions provided by citus. These functions help in providing additional distributed functionality to citus other than the standard SQL commands.

#### J.5.7.5.1.1. Table and Shard DDL

`citus_schema_distribute (schemaname regnamespace) returns void`

Converts existing regular schemas into distributed schemas, which are automatically associated with individual co-location groups such that the tables created in those schemas will be automatically converted to co-located distributed tables without a shard key. The process of distributing the schema will automatically assign and move it to an existing node in the cluster.

Arguments:

- *schemaname* — the name of the schema, which needs to be distributed.

The example below shows how to distribute three schemas named `tenant_a`, `tenant_b`, and `tenant_c`. For more examples, see the [Microservices](#) section:

```
SELECT citus_schema_distribute('tenant_a');
SELECT citus_schema_distribute('tenant_b');
SELECT citus_schema_distribute('tenant_c');
```

`citus_schema_undistribute (schemaname regnamespace) returns void`

Converts an existing distributed schema back into a regular schema. The process results in the tables and data being moved from the current node back to the coordinator node in the cluster.

**Arguments:**

- *schemaname* — the name of the schema, which needs to be distributed.

The example below shows how to convert three different distributed schemas back into regular schemas. For more examples, see the [Microservices](#) section:

```
SELECT citus_schema_undistribute('tenant_a');
SELECT citus_schema_undistribute('tenant_b');
SELECT citus_schema_undistribute('tenant_c');
```

```
create_distributed_table (table_name regclass, distribution_column text, distribu-
tion_type citus.distribution_type, colocate_with text, shard_count int) returns void
```

Defines a distributed table and create its shards if it is a hash-distributed table. This function takes in a table name, the distribution column, and an optional distribution method and inserts appropriate metadata to mark the table as distributed. The function defaults to hash distribution if no distribution method is specified. If the table is hash-distributed, the function also creates worker shards based on the shard count configuration value. If the table contains any rows, they are automatically distributed to worker nodes.

**Arguments:**

- *table\_name* — the name of the table, which needs to be distributed.
- *distribution\_column* — the column on which the table is to be distributed.
- *distribution\_type* — an optional distribution method. The default value is `hash`.
- *colocate\_with* — include current table in the co-location group of another table. This is an optional argument. By default tables are co-located when they are distributed by columns of the same type with the same shard count. If you want to break this co-location later, you can use the [update\\_distributed\\_table\\_colocation](#) function. Possible values for this argument are `default`, which is the default value, `none` to start a new co-location group, or the name of another table to co-locate with the table. To learn more, see the [Co-Locating Tables](#) section.

Keep in mind that the default value of the *colocate\_with* argument does implicit co-location. As explained in the [Table Co-Location](#) section, this can be a great thing when tables are related or will be joined. However, when two tables are unrelated but happen to use the same datatype for their distribution columns, accidentally co-locating them can decrease performance during [shard rebalancing](#). The table shards will be moved together unnecessarily in a “cascade”. If you want to break this implicit co-location, you can use the [update\\_distributed\\_table\\_colocation](#) function.

If a new distributed table is not related to other tables, it is best to specify `colocate_with => 'none'`.

- *shard\_count* — the number of shards to create for the new distributed table. This is an optional argument. When specifying *shard\_count* you cannot specify a value of *colocate\_with* other than `none`. To change the shard count of an existing table or co-location group, use the [alter\\_distributed\\_table](#) function.

Allowed values for the *shard\_count* argument are between 1 and 64000. For guidance on choosing the optimal value, see the [Shard Count](#) section.

This example informs the database that the `github_events` table should be distributed by hash on the `repo_id` column. For more examples, see the [Creating and Modifying Distributed Objects \(DDL\)](#) section:

```
SELECT create_distributed_table('github_events', 'repo_id');
```

```
-- Alternatively, to be more explicit:
```

```
SELECT create_distributed_table('github_events', 'repo_id',
                                colocate_with => 'github_repo');
```

`truncate_local_data_after_distributing_table` (function\_name regclass) returns void

Truncates all local rows after distributing a table and prevent constraints from failing due to outdated local records. The truncation cascades to tables having a foreign key to the designated table. If the referring tables are not themselves distributed, then truncation is forbidden until they are to protect referential integrity:

```
ERROR:  cannot truncate a table referenced in a foreign key constraint by a local
table
```

Truncating local coordinator node table data is safe for distributed tables because their rows, if they have any, are copied to worker nodes during distribution.

Arguments:

- *table\_name* — the name of the distributed table whose local counterpart on the coordinator node should be truncated.

The example below shows how to use the function:

```
-- Requires that argument is a distributed table
SELECT truncate_local_data_after_distributing_table('public.github_events');
```

`undistribute_table` (table\_name regclass, cascade\_via\_foreign\_keys boolean) returns void

Undoes the action of the [create\\_distributed\\_table](#) or [create\\_reference\\_table](#) functions. Undistributing moves all data from shards back into a local table on the coordinator node (assuming the data can fit), then deletes the shards.

`citus` will not undistribute tables that have, or are referenced by, foreign keys, unless the *cascade\_via\_foreign\_keys* argument is set to `true`. If this argument is `false` (or omitted), then you must manually drop the offending foreign key constraints before undistributing.

Arguments:

- *table\_name* — the name of the distributed or reference table to undistribute.
- *cascade\_via\_foreign\_keys* — when this optional argument is set to `true`, the function also undistributes all tables that are related to *table\_name* through foreign keys. Use caution with this argument because it can potentially affect many tables. The default value is `false`.

The example below shows how to distribute the `github_events` table and then undistribute it:

```
-- First distribute the table
SELECT create_distributed_table('github_events', 'repo_id');

-- Undo that and make it local again
SELECT undistribute_table('github_events');
```

`alter_distributed_table` (table\_name regclass, distribution\_column text, shard\_count int, colocate\_with text, cascade\_to\_colocated boolean) returns void

Changes the distribution column, shard count or co-location properties of a distributed table.

Arguments:

- *table\_name* — the name of the distributed table, which will be altered.
- *distribution\_column* — the name of the new distribution column. The default value of this optional argument is `NULL`.
- *shard\_count* — the new shard count. The default value of this optional argument is `NULL`.
- *colocate\_with* — the table that the current distributed table will be co-located with. Possible values are `default`, `none` to start a new co-location group, or the name of another table with which to co-locate. The default value of this optional argument is `default`.

- *cascade\_to\_colocated*. When this argument is set to `true`, *shard\_count* and *colocate\_with* changes will also be applied to all of the tables that were previously co-located with the table, and the co-location will be preserved. If it is `false`, the current co-location of this table will be broken. The default value of this optional argument is `false`.

The example below shows how to use the function:

```
-- Change distribution column
SELECT alter_distributed_table('github_events', distribution_column:='event_id');

-- Change shard count of all tables in colocation group
SELECT alter_distributed_table('github_events', shard_count:=6,
    cascade_to_colocated:=true);

-- Change colocation
SELECT alter_distributed_table('github_events', colocate_with:='another_table');
```

`alter_table_set_access_method (table_name regclass, access_method text)` returns void

Changes access method of a table (e.g. heap or [columnar](#)).

Arguments:

- *table\_name* — the name of the table whose access method will change.
- *access\_method* — the name of the new access method.

The example below shows how to use the function:

```
SELECT alter_table_set_access_method('github_events', 'columnar');
```

`remove_local_tables_from_metadata ()` returns void

Removes local tables from metadata of the citus extension that no longer need to be there. (See the [citus.enable\\_local\\_reference\\_table\\_foreign\\_keys](#) configuration parameter.)

Usually if a local table is in citus metadata, there is a reason, such as the existence of foreign keys between the table and a reference table. However, if `citus.enable_local_reference_table_foreign_keys` is disabled, citus will no longer manage metadata in that situation, and unnecessary metadata can persist until manually cleaned.

`create_reference_table (table_name regclass)` returns void

Defines a small reference or dimension table. This function takes in a table name, and creates a distributed table with just one shard, replicated to every worker node.

Arguments:

- *table\_name* — the name of the small dimension or reference table, which needs to be distributed.

The example below informs the database that the `nation` table should be defined as a reference table:

```
SELECT create_reference_table('nation');
```

`citus_add_local_table_to_metadata (table_name regclass, cascade_via_foreign_keys boolean)` returns void

Adds a local Postgres Pro table into citus metadata. A major use case for this function is to make local tables on the coordinator accessible from any node in the cluster. This is mostly useful when running queries from other nodes. The data associated with the local table stays on the coordinator, only its schema and metadata are sent to the workers.

Note that adding local tables to the metadata comes at a slight cost. When you add the table, citus must track it in the [pg\\_dist\\_partition](#). Local tables that are added to metadata inherit the same

limitations as reference tables (see the [Creating and Modifying Distributed Objects \(DDL\)](#) and [SQL Support and Workarounds](#) sections).

If you use the [undistribute\\_table](#) function, citus will automatically remove the resulting local tables from metadata, which eliminates such limitations on those tables.

Arguments:

- *table\_name* — the name of the table on the coordinator to be added to citus metadata.
- *cascade\_via\_foreign\_keys* — when this optional argument is set to `true`, the function adds other tables that are in a foreign key relationship with given table into metadata automatically. Use caution with this argument, because it can potentially affect many tables. The default value is `false`.

The example below informs the database that the `nation` table should be defined as a coordinator-local table, accessible from any node:

```
SELECT citus_add_local_table_to_metadata('nation');
```

`update_distributed_table_colocation (table_name regclass, colocate_with text) returns void`

Updates co-location of a distributed table. This function can also be used to break co-location of a distributed table. citus will implicitly co-locate two tables if the distribution column is the same type, this can be useful if the tables are related and will do some joins. If table A and B are co-located and table A gets rebalanced, table B will also be rebalanced. If table B does not have a replica identity, the rebalance will fail. Therefore, this function can be useful breaking the implicit co-location in that case. Note that this function does not move any data around physically.

Arguments:

- *table\_name* — the name of the table co-location of which will be updated.
- *colocate\_with* — the table with which the table should be co-located.

If you want to break the co-location of a table, specify `colocate_with => 'none'`.

The example below shows that co-location of table A is updated as co-location of table B:

```
SELECT update_distributed_table_colocation('A', colocate_with => 'B');
```

Assume that table A and table B are co-located (possibly implicitly). If you want to break the co-location, do the following:

```
SELECT update_distributed_table_colocation('A', colocate_with => 'none');
```

Now, assume that tables A, B, C, and D are co-located and you want to co-locate table A with B and table C with table D:

```
SELECT update_distributed_table_colocation('C', colocate_with => 'none');
SELECT update_distributed_table_colocation('D', colocate_with => 'C');
```

If you have a hash-distributed table named `none` and you want to update its co-location, you can do:

```
SELECT update_distributed_table_colocation('"none"', colocate_with =>
    'some_other_hash_distributed_table');
```

`create_distributed_function (function_name regprocedure, distribution_arg_name text, colocate_with text, force_delegation bool) returns void`

Propagates a function from the coordinator node to workers and marks it for distributed execution. When a distributed function is called on the coordinator, citus uses the value of the *distribution\_arg\_name* argument to pick a worker node to run the function. Calling the function on workers increases parallelism and can bring the code closer to data in shards for lower latency.

Note that the Postgres Pro search path is not propagated from the coordinator to workers during distributed function execution, so distributed function code should fully qualify the names of database objects. Also notices emitted by the functions will not be displayed to the user.

Arguments:

- *function\_name* — the name of the function to be distributed. The name must include the function parameter types in parentheses because multiple functions can have the same name in Postgres Pro. For instance, 'foo(int)' is different from 'foo(int, text)'.
- *distribution\_arg\_name* — the argument name by which to distribute. For convenience (or if the function arguments do not have names), a positional placeholder is allowed, such as '\$1'. If this argument is not specified, then the function named by *function\_name* is merely created on the workers. If worker nodes are added in the future, the function will automatically be created there too. This is an optional argument.
- *colocate\_with* — when the distributed function reads or writes to a distributed table (or more generally [co-locating tables](#)), be sure to name that table using the this argument. This ensures that each invocation of the function runs on the worker node containing relevant shards. This is an optional argument.
- *force\_delegation*. The default value is NULL.

The example below shows how to use the function:

```
-- An example function that updates a hypothetical
-- event_responses table, which itself is distributed by event_id
CREATE OR REPLACE FUNCTION
    register_for_event(p_event_id int, p_user_id int)
RETURNS void LANGUAGE plpgsql AS $fn$
BEGIN
    INSERT INTO event_responses VALUES ($1, $2, 'yes')
    ON CONFLICT (event_id, user_id)
    DO UPDATE SET response = EXCLUDED.response;
END;
$fn$;

-- Distribute the function to workers, using the p_event_id argument
-- to determine which shard each invocation affects, and explicitly
-- collocating with event_responses which the function updates
SELECT create_distributed_function(
    'register_for_event(int, int)', 'p_event_id',
    colocate_with := 'event_responses'
);

alter_columnar_table_set      (table_name      regclass,      chunk_group_row_limit      int,
stripe_row_limit int, compression name, compression_level int) returns void
```

Changes settings on a [columnar table](#). Calling this function on a non-columnar table gives an error. All arguments except the *table\_name* are optional.

To view current options for all columnar tables, consult this table:

```
SELECT * FROM columnar.options;
```

The default values for columnar settings for newly created tables can be overridden with these configuration parameters:

- columnar.compression
- columnar.compression\_level
- columnar.stripe\_row\_count
- columnar.chunk\_row\_count

Arguments:

- *table\_name* — the name of the columnar table.
- *chunk\_row\_count* — the maximum number of rows per chunk for newly inserted data. Existing chunks of data will not be changed and may have more rows than this maximum value. The default value is 10000.
- *stripe\_row\_count* — the maximum number of rows per stripe for newly inserted data. Existing stripes of data will not be changed and may have more rows than this maximum value. The default value is 150000.
- *compression* — the compression type for the newly inserted data. Existing data will not be re-compressed or decompressed. The default and generally suggested value is *zstd* (if support has been compiled in). Allowed values are *none*, *pglz*, *zstd*, *lz4*, and *lz4hc*.
- *compression\_level*. Allowed values are from 1 to 19. If the compression method does not support the level chosen, the closest level will be selected instead.

The example below shows how to use the function:

```
SELECT alter_columnar_table_set(  
    'my_columnar_table',  
    compression => 'none',  
    stripe_row_count => 10000);
```

`create_time_partitions (table_name regclass, partition_interval interval, end_at timestamp, start_from timestamp)` returns boolean

Creates partitions of a given interval to cover a given range of time. Returns `true` if new partitions are created and `false` if they already exist.

Arguments:

- *table\_name* — the table for which to create new partitions. The table must be partitioned on one column of type `date`, `timestamp`, or `timestampz`.
- *partition\_interval* — the interval of time, such as `'2 hours'`, or `'1 month'`, to use when setting ranges on new partitions.
- *end\_at* — create partitions up to this time. The last partition will contain the point *end\_at* and no later partitions will be created.
- *start\_from* — pick the first partition so that it contains the point *start\_from*. The default value is `now()`.

The example below shows how to use the function:

```
-- Create a year's worth of monthly partitions  
-- in table foo, starting from the current time
```

```
SELECT create_time_partitions(  
    table_name      := 'foo',  
    partition_interval := '1 month',  
    end_at          := now() + '12 months'  
);
```

`drop_old_time_partitions (table_name regclass, older_than timestamp)`

Removes all partitions whose intervals fall before a given timestamp. In addition to using this function, you might consider the [alter\\_old\\_partitions\\_set\\_access\\_method](#) function to compress the old partitions with columnar storage.

Arguments:

- *table\_name* — the table for which to remove partitions. The table must be partitioned on one column of type `date`, `timestamp`, or `timestampz`.
- *older\_than* — drop partitions whose upper limit is less than or equal to the *older\_than* value.

The example below shows how to use the procedure:

```
-- Drop partitions that are over a year old

CALL drop_old_time_partitions('foo', now() - interval '12 months');

alter_old_partitions_set_access_method (parent_table_name regclass, older_than time-
stampz, new_access_method name)
```

In the [timeseries data](#) use case tables are often partitioned by time and old partitions are compressed into read-only columnar storage.

Arguments:

- *parent\_table\_name* — the table for which to change partitions. The table must be partitioned on one column of type `date`, `timestamp`, or `timestampz`.
- *older\_than* — change partitions whose upper limit is less than or equal to the *older\_than* value.
- *new\_access\_method*. Allowed values are `heap` for row-based storage or `columnar` for columnar storage.

The example below shows how to use the procedure:

```
CALL alter_old_partitions_set_access_method(
    'foo', now() - interval '6 months',
    'columnar'
);
```

#### J.5.7.5.1.2. Metadata / Configuration Information

```
citus_add_node (nodename text, nodeport integer, groupid integer, noderole noderole,
nodecluster name) returns integer
```

### Note

This function requires database superuser access to run.

Registers a new node addition in the cluster in the citus metadata table [pg\\_dist\\_node](#). It also copies reference tables to the new node. The function returns the `nodeid` column from the newly inserted row in `pg_dist_node`.

If you call the function on a single-node cluster, be sure to call the [citus\\_set\\_coordinator\\_host](#) function first.

Arguments:

- *nodename* — the DNS name or IP address of the new node to be added.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.
- *groupid* — the group of one primary server and its secondary servers, relevant only for streaming replication. Be sure to set this argument to a value greater than zero, since zero is reserved for the coordinator node. The default value is `-1`.
- *noderole* — the role of the node. Allowed values are `primary` and `secondary`. The default value is `primary`.
- *nodecluster* — the name of the cluster. The default value is `default`.

The example below shows how to use the function:

```
SELECT * FROM citus_add_node('new-node', 12345);
citus_add_node
-----
              7
(1 row)
```

```
citus_update_node (node_id int, new_node_name text, new_node_port int, force bool,  
lock_cooldown int) returns void
```

### Note

This function requires database superuser access to run.

Changes the hostname and port for a node registered in the citus metadata table [pg\\_dist\\_node](#).

#### Arguments:

- *node\_id* — the node ID from the `pg_dist_node` table.
- *new\_node\_name* — the updated DNS name or IP address for the node.
- *new\_node\_port* — the updated port on which Postgres Pro is listening on the worker node.
- *force*. The default value is `false`.
- *lock\_cooldown*. The default value is 10000.

The example below shows how to use the function:

```
SELECT * FROM citus_update_node(123, 'new-address', 5432);
```

```
citus_set_node_property (nodename text, nodeport integer, property text, value boolean)  
returns void
```

Changes properties in the citus metadata table [pg\\_dist\\_node](#). Currently it can change only the `shouldhaveshard` property.

#### Arguments:

- *nodename* — the DNS name or IP address for the node.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.
- *property* — the column to change in `pg_dist_node`, currently only the `shouldhaveshard` property is supported.
- *value* — the new value for the column.

The example below shows how to use the function:

```
SELECT * FROM citus_set_node_property('localhost', 5433, 'shouldhaveshard', false);
```

```
citus_add_inactive_node (nodename text, nodeport integer, groupid integer, noderole node-  
role, nodecluster name) returns integer
```

### Note

This function requires database superuser access to run.

Similarly to the [citus\\_add\\_node](#) function, registers a new node in [pg\\_dist\\_node](#). However, it marks the new node as inactive, meaning no shards will be placed there. Also it does *not* copy reference tables to the new node. The function returns the `nodeid` column from the newly inserted row in `pg_dist_node`.

#### Arguments:

- *nodename* — the DNS name or IP address of the new node to be added.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.
- *groupid* — the group of one primary server and zero or more secondary servers, relevant only for streaming replication. The default is `-1`.
- *noderole* — the role of the node. Allowed values are `primary` and `secondary`. The default value is `primary`.
- *nodecluster* — the name of the cluster. The default value is `default`.

The example below shows how to use the function:

```
SELECT * FROM citus_add_inactive_node('new-node', 12345);
citus_add_inactive_node
-----
                                7
(1 row)
```

`citus_activate_node (nodename text, nodeport integer) returns integer`

### Note

This function requires database superuser access to run.

Marks a node as active in the citus metadata table [pg\\_dist\\_node](#) and copies reference tables to the node. Useful for nodes added via [citus\\_add\\_inactive\\_node](#). The function returns the `nodeid` column from the newly inserted row in `pg_dist_node`.

Arguments:

- *nodename* — the DNS name or IP address of the new node to be added.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.

The example below shows how to use the function:

```
SELECT * FROM citus_activate_node('new-node', 12345);
citus_activate_node
-----
                                7
(1 row)
```

`citus_disable_node (nodename text, nodeport integer, synchronous bool) returns void`

### Note

This function requires database superuser access to run.

This function is the opposite from [citus\\_activate\\_node](#). It marks a node as inactive in the citus metadata table [pg\\_dist\\_node](#), removing it from the cluster temporarily. The function also deletes all reference table placements from the disabled node. To reactivate the node, just call [citus\\_activate\\_node](#) again.

Arguments:

- *nodename* — the DNS name or IP address of the node to be disabled.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.
- *synchronous*. The default value is `false`.

The example below shows how to use the function:

```
SELECT * FROM citus_disable_node('new-node', 12345);
```

`citus_add_secondary_node (nodename text, nodeport integer, primaryname text, primaryport integer, nodecluster name) returns integer`

### Note

This function requires database superuser access to run.

Registers a new secondary node in the cluster for an existing primary node. The function updates the citus [pg\\_dist\\_node](#) metadata table. The function returns the `nodeid` column for the secondary node from the inserted row in `pg_dist_node`.

#### Arguments:

- *nodename* — the DNS name or IP address of the new node to be added.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.
- *primaryname* — the DNS name or IP address of the primary node for this secondary.
- *primaryport* — the port on which Postgres Pro is listening on the primary node.
- *nodecluster* — the name of the cluster. The default value is `default`.

The example below shows how to use the function:

```
SELECT * FROM citus_add_secondary_node('new-node', 12345, 'primary-node', 12345);
citus_add_secondary_node
-----
                                7
(1 row)
```

`citus_remove_node` (*nodename* text, *nodeport* integer) returns void

### Note

This function requires database superuser access to run.

Removes the specified node from the [pg\\_dist\\_node](#) metadata table. This function will error out if there are existing shard placements on this node. Thus, before using this function, the shards will need to be moved off that node.

#### Arguments:

- *nodename* — the DNS name of the node to be removed.
- *nodeport* — the port on which Postgres Pro is listening on the worker node.

The example below shows how to use the function:

```
SELECT citus_remove_node('new-node', 12345);
citus_remove_node
-----
(1 row)
```

`citus_get_active_worker_nodes` () returns setof record

Returns active worker host names and port numbers as a list of tuples where each tuple contains the following information:

- *node\_name* — the DNS name of the worker node.
- *node\_port* — the port on the worker node on which the database server is listening.

The example below shows the output of the function:

```
SELECT * FROM citus_get_active_worker_nodes();
 node_name | node_port
-----+-----
 localhost |         9700
 localhost |         9702
 localhost |         9701
(3 rows)
```

`citus_backend_gpid ()` returns bigint

Returns the global process identifier (GPID) for the Postgres Pro backend serving the current session. The GPID value encodes both a node in the citus cluster and the operating system process ID of Postgres Pro on that node. The GPID is returned in the following form: (node ID \* 10,000,000,000) + process ID.

`citus` extends the Postgres Pro [server signaling functions](#) `pg_cancel_backend` and `pg_terminate_backend` so that they accept GPIDs. In `citus`, calling these functions on one node can affect a backend running on another node.

The example below shows the output of the function:

```
SELECT citus_backend_gpid();
citus_backend_gpid
-----
100000002055
```

`citus_check_cluster_node_health ()` returns setof record

Checks connectivity between all nodes. If there are N nodes, this function checks all N<sup>2</sup> connections between them. The function returns the list of tuples where each tuple contains the following information:

- *from\_nodename* — the DNS name of the source worker node.
- *from\_nodeport* — the port on the source worker node on which the database server is listening.
- *to\_nodename* — the DNS name of the destination worker node.
- *to\_nodeport* — the port on the destination worker node on which the database server is listening.
- *result* — whether a connection could be established.

The example below shows the output of the function:

```
SELECT * FROM citus_check_cluster_node_health();
from_nodename | from_nodeport | to_nodename | to_nodeport | result
-----+-----+-----+-----+-----
localhost    | 1400          | localhost   | 1400        | t
localhost    | 1400          | localhost   | 1401        | t
localhost    | 1400          | localhost   | 1402        | t
localhost    | 1401          | localhost   | 1400        | t
localhost    | 1401          | localhost   | 1401        | t
localhost    | 1401          | localhost   | 1402        | t
localhost    | 1402          | localhost   | 1400        | t
localhost    | 1402          | localhost   | 1401        | t
localhost    | 1402          | localhost   | 1402        | t

(9 rows)
```

`citus_set_coordinator_host (host text, port integer, node_role noderole, node_cluster name)` returns void

This function is required when adding worker nodes to a citus cluster, which was created initially as a [single-node cluster](#). When the coordinator registers a new worker, it adds a coordinator hostname from the value of the `citus.local_hostname` configuration parameter, which is `localhost` by default. The worker would attempt to connect to `localhost` to talk to the coordinator, which is obviously wrong.

Thus, the system administrator should call this function before calling the `citus_add_node` function in a single-node cluster.

Arguments:

- *host* — the DNS name of the coordinator node.
- *port* — the port on which the coordinator lists for Postgres Pro connections. The default value of this optional argument is `current_setting('port')`.
- *node\_role* — the role of the node. The default value of this optional argument is `primary`.
- *node\_cluster* — the name of the cluster. The default value of this optional argument is `default`.

The example below shows how to use the function:

```
-- Assuming we are in a single-node cluster

-- First establish how workers should reach us
SELECT citus_set_coordinator_host('coord.example.com', 5432);

-- Then add a worker
SELECT * FROM citus_add_node('worker1.example.com', 5432);

get_shard_id_for_distribution_column (table_name regclass, distribution_value "any") re-
turns bigint
```

citus assigns every row of a distributed table to a shard based on the value of the row's distribution column and the table's method of distribution. In most cases the precise mapping is a low-level detail that the database administrator can ignore. However, it can be useful to determine a row's shard either for manual database maintenance tasks or just to satisfy curiosity. The `get_shard_id_for_distribution_column` function provides this info for hash-distributed tables as well as reference tables and returns the shard ID that citus associates with the distribution column value for the given table.

#### Arguments:

- *table\_name* — the name of the distributed table.
- *distribution\_value* — the value of the distribution column. The default value is `NULL`.

The example below shows how to use the function:

```
SELECT get_shard_id_for_distribution_column('my_table', 4);

get_shard_id_for_distribution_column
-----
                                540007

(1 row)

column_to_column_name (table_name regclass, column_var_text text) returns text
```

Translates the `partkey` column of the [pg\\_dist\\_partition](#) table into a textual column name. This is useful to determine the distribution column of a distributed table. The function returns the distribution column name of the *table\_name* table. To learn more, see the [Finding the Distribution Column For a Table](#) section.

#### Arguments:

- *table\_name* — name of the distributed table.
- *column\_var\_text* — value of `partkey` column in the `pg_dist_partition` table.

The example below shows how to use the function:

```
-- Get distribution column name for products table

SELECT column_to_column_name(logicalrelid, partkey) AS dist_col_name
FROM pg_dist_partition
WHERE logicalrelid='products'::regclass;

| dist_col_name |
```

`citus_relation_size` (logicalrelid regclass) returns bigint

Returns the disk space used by all the shards of the specified distributed table. This includes the size of the “main fork” but excludes the visibility map and free space map for the shards.

Arguments:

- *logicalrelid* — the name of the distributed table.

The example below shows how to use the function:

```

SELECT pg_size_pretty(citus_relation_size('github_events'));
pg_size_pretty
-----
23 MB
  
```

`citus_table_size` (logicalrelid regclass) returns bigint

Returns the disk space used by all the shards of the specified distributed table, excluding indexes (but including TOAST, free space map, and visibility map).

Arguments:

- *logicalrelid* — the name of the distributed table.

The example below shows how to use the function:

```

SELECT pg_size_pretty(citus_table_size('github_events'));
pg_size_pretty
-----
37 MB
  
```

`citus_total_relation_size` (logicalrelid regclass, fail\_on\_error boolean) returns bigint

Returns the total disk space used by the all the shards of the specified distributed table, including all indexes and TOAST data.

Arguments:

- *logicalrelid* — the name of the distributed table.
- *fail\_on\_error*. The default value is `true`.

The example below shows how to use the function:

```

SELECT pg_size_pretty(citus_total_relation_size('github_events'));
pg_size_pretty
-----
73 MB
  
```

`citus_stat_statements_reset` () returns void

Removes all rows from the [citus\\_stat\\_statements](#) table. Note that this works independently from the [pg\\_stat\\_statements\\_reset](#) function. To reset all stats, call both functions.

#### J.5.7.5.1.3. Cluster Management And Repair Functions

`citus_move_shard_placement` (shard\_id bigint, source\_node\_name text, source\_node\_port integer, target\_node\_name text, target\_node\_port integer, shard\_transfer\_mode citus.shard\_transfer\_mode) returns void

Moves a given shard (and shards co-located with it) from one node to another. It is typically used indirectly during shard rebalancing rather than being called directly by a database administrator.

There are two ways to move the data: blocking or non-blocking. The blocking approach means that during the move all modifications to the shard are paused. The second way, which avoids blocking shard writes, relies on Postgres Pro 10 logical replication.

After a successful move operation, shards in the source node get deleted. If the move fails at any point, this function throws an error and leaves the source and target nodes unchanged.

Arguments:

- *shard\_id* — the ID of the shard to be moved.
- *source\_node\_name* — the DNS name of the node on which the healthy shard placement is present (“source” node).
- *source\_node\_port* — the port on the source worker node on which the database server is listening.
- *target\_node\_name* — the DNS name of the node on which the invalid shard placement is present (“target” node).
- *target\_node\_port* — the port on the target worker node on which the database server is listening.
- *shard\_transfer\_mode* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker `COPY` command. The allowed values of this optional argument are:
  - *auto* — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - *force\_logical* — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - *block\_writes* — use `COPY` (blocking writes) for tables lacking primary key or replica identity.

The example below shows how to use the function:

```
SELECT citus_move_shard_placement(12345, 'from_host', 5432, 'to_host', 5432);
```

`citus_rebalance_start` (rebalance\_strategy name, drain\_only boolean, shard\_transfer\_mode citus.shard\_transfer\_mode) returns bigint

Moves table shards to make them evenly distributed among the workers. It begins a background job to do the rebalancing and returns immediately.

The rebalancing process first calculates the list of moves it needs to make in order to ensure that the cluster is balanced within the given threshold. Then, it moves shard placements one by one from the source node to the destination node and updates the corresponding shard metadata to reflect the move.

Every shard is assigned a cost when determining whether shards are “evenly distributed”. By default each shard has the same cost (a value of 1), so distributing to equalize the cost across workers is the same as equalizing the number of shards on each. The constant cost strategy is called `by_shard_count` and is the default rebalancing strategy.

The `by_shard_count` strategy is appropriate under these circumstances:

- The shards are roughly the same size.
- The shards get roughly the same amount of traffic.
- Worker nodes are all the same size/type.
- Shards have not been pinned to particular workers.

If any of these assumptions do not hold, then rebalancing using the `by_shard_count` strategy can result in a bad plan.

If any of these assumptions do not hold, then rebalancing using the `by_shard_count` strategy can result in a bad plan.

The default rebalancing strategy is `by_disk_size`. You can always customize the strategy, using the `rebalance_strategy` parameter.

It is advisable to call the [get\\_rebalance\\_table\\_shards\\_plan](#) function before `citus_rebalance_start` to see and verify the actions to be performed.

Arguments:

- *rebalance\_strategy* — name of a strategy in the [pg\\_dist\\_rebalance\\_strategy](#) table. If this argument is omitted, the function chooses the default strategy, as indicated in the table. The default value of this optional argument is `NULL`.
- *drain\_only*. When `true`, move shards off worker nodes who have `shouldhaveshards` set to `false` in the [pg\\_dist\\_node](#) table; move no other shards. The default value of this optional argument is `false`.
- *shard\_transfer\_mode* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker `COPY` command. The allowed values of this optional argument are:
  - `auto` — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - `force_logical` — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - `block_writes` — use `COPY` (blocking writes) for tables lacking primary key or replica identity.

The example below will attempt to rebalance shards:

```
SELECT citus_rebalance_start();
NOTICE: Scheduling...
NOTICE: Scheduled as job 1337.
DETAIL: Rebalance scheduled as background job 1337.
HINT: To monitor progress, run: SELECT details FROM citus_rebalance_status();
```

`citus_rebalance_status ()` returns table

Allows you to monitor the progress of the rebalance. Returns immediately, while the rebalance continues as a background job.

To get general information about the rebalance, you can select all columns from the status. This shows the basic state of the job:

```
SELECT * FROM citus_rebalance_status();
```

| job_id | state   | job_type  | description                  | started_at                    | finished_at                   | details |
|--------|---------|-----------|------------------------------|-------------------------------|-------------------------------|---------|
| 4      | running | rebalance | Rebalance colocation group 1 | 2022-08-09 21:57:27.833055+02 | 2022-08-09 21:57:27.833055+02 | { ... } |

Rebalancer specifics live in the `details` column, in JSON format:

```
SELECT details FROM citus_rebalance_status();
```

```
{
  "phase": "copy",
  "phase_index": 1,
  "phase_count": 3,
  "last_change": "2022-08-09 21:57:27",
  "colocations": {
    "1": {
      "shard_moves": 30,
      "shard_moved": 29,
      "last_move": "2022-08-09 21:57:27"
    },
    "1337": {
      "shard_moves": 130,
```

```
        "shard_moved": 0
    }
}
```

`citusb_rebalance_stop ()` returns void

Cancels the rebalance in progress, if any.

`citusb_rebalance_wait ()` returns void

Blocks until a running rebalance is complete. If no rebalance is in progress when this function is called, then the function returns immediately.

The function can be useful for scripts or benchmarking.

`get_rebalance_table_shards_plan ()` returns table

Outputs the planned shard movements of the `citusb_rebalance_start` function without performing them. While it is unlikely, this function can output a slightly different plan than what a `citusb_rebalance_start` call with the same arguments will do. This could happen because they are not executed at the same time, so facts about the cluster, e.g. disk space, might differ between the calls. The function returns tuples containing the following columns:

- `table_name` — the table whose shards would move.
- `shardid` — the shard in question.
- `shard_size` — the size, in bytes.
- `sourcename` — the hostname of the source node.
- `sourceport` — the port of the source node.
- `targetname` — the hostname of the destination node.
- `targetport` — the port of the destination node.

#### Arguments:

- A superset of the arguments for the `citusb_rebalance_start` function: *relation*, *threshold*, *max\_shard\_moves*, *excluded\_shard\_list*, and *drain\_only*.

`get_rebalance_progress ()` returns table

Once the shard rebalance begins, this function lists the progress of every shard involved. It monitors the moves planned and executed by the `citusb_rebalance_start` function. The function returns tuples containing the following columns:

- `sessionid` — the Postgres Pro PID of the rebalance monitor.
- `table_name` — the table whose shards are moving.
- `shardid` — the shard in question.
- `shard_size` — the size of the shard, in bytes.
- `sourcename` — the hostname of the source node.
- `sourceport` — the port of the source node.
- `targetname` — the hostname of the destination node.
- `targetport` — the port of the destination node.
- `progress`. The following values may be returned: 0 — waiting to be moved, 1 — moving, 2 — complete.
- `source_shard_size` — the size of the shard on the source node, in bytes.
- `target_shard_size` — the size of the shard on the target node, in bytes.

The example below shows how to use the function:

```
SELECT * FROM get_rebalance_progress();
```

|            |            |          |                   |                   |            |  |
|------------|------------|----------|-------------------|-------------------|------------|--|
| sessionid  | table_name | shardid  | shard_size        | sourcename        | sourceport |  |
| targetname | targetport | progress | source_shard_size | target_shard_size |            |  |

|               |     |        |         |               |      |        |
|---------------|-----|--------|---------|---------------|------|--------|
| 7083          | foo | 102008 | 1204224 | n1.foobar.com | 5432 |        |
| n4.foobar.com |     | 5432   | 0       | 1204224       |      | 0      |
| 7083          | foo | 102009 | 1802240 | n1.foobar.com | 5432 |        |
| n4.foobar.com |     | 5432   | 0       | 1802240       |      | 0      |
| 7083          | foo | 102018 | 614400  | n2.foobar.com | 5432 |        |
| n4.foobar.com |     | 5432   | 1       | 614400        |      | 354400 |
| 7083          | foo | 102019 | 8192    | n3.foobar.com | 5432 |        |
| n4.foobar.com |     | 5432   | 2       | 0             |      | 8192   |

`citus_add_rebalance_strategy` (name name, shard\_cost\_function regproc, node\_capacity\_function regproc, shard\_allowed\_on\_node\_function regproc, default\_threshold float4, minimum\_threshold float4, improvement\_threshold float4) returns void

Append a row to the [pg\\_dist\\_rebalance\\_strategy](#) table.

Arguments:

- *name* — the identifier for the new strategy.
- *shard\_cost\_function* — identifies the function used to determine the “cost” of each shard.
- *node\_capacity\_function* — identifies the function to measure node capacity.
- *shard\_allowed\_on\_node\_function* — identifies the function that determines which shards can be placed on which nodes.
- *default\_threshold* — floating point threshold that tunes how precisely the cumulative shard cost should be balanced between nodes.
- *minimum\_threshold* — safeguard column that holds the minimum value allowed for the threshold argument of the [citus\\_rebalance\\_start](#) function. The default value is 0.
- *improvement\_threshold*. The default value is 0.

`citus_set_default_rebalance_strategy` (name text) returns void

Update the [pg\\_dist\\_rebalance\\_strategy](#) table changing the strategy named by its argument to be the default chosen when rebalancing shards.

Arguments:

- *name* — the name of the strategy in the [pg\\_dist\\_rebalance\\_strategy](#) table.

The example below shows how to use the function:

```
SELECT citus_set_default_rebalance_strategy('by_disk_size');
```

`citus_remote_connection_stats` () returns setof record

Shows the number of active connections to each remote node.

The example below shows how to use the function:

```
SELECT * FROM citus_remote_connection_stats();
```

```
.
  hostname      | port | database_name | connection_count_to_node
-----+-----+-----+-----
citus_worker_1 | 5432 | postgres      | 3
(1 row)
```

`citus_drain_node` (nodename text, nodeport integer, shard\_transfer\_mode citus.shard\_transfer\_mode, rebalance\_strategy name) returns void

Moves shards off the designated node and onto other nodes who have `shouldhaveshards` set to true in the [pg\\_dist\\_node](#) table. This function is designed to be called prior to removing a node from the cluster, i.e. turning the node's physical server off.

Arguments:

- *nodename* — the DNS name of the node to be drained.
- *nodeport* — the port number of the node to be drained.
- *shard\_transfer\_mode* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker `COPY` command. The allowed values of this optional argument are:
  - *auto* — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - *force\_logical* — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - *block\_writes* — use `COPY` (blocking writes) for tables lacking primary key or replica identity.
- *rebalance\_strategy* — the name of a strategy in the [pg\\_dist\\_rebalance\\_strategy](#) table. If this argument is omitted, the function chooses the default strategy, as indicated in the table. The default value of this optional argument is `NULL`.

Here are the typical steps to remove a single node (for example '10.0.0.1' on a standard Postgres Pro port):

1. Drain the node.

```
SELECT * FROM citus_drain_node('10.0.0.1', 5432);
```

2. Wait until the command finishes.

3. Remove the node.

When draining multiple nodes it is recommended to use the [citus\\_rebalance\\_start](#) function instead. Doing so allows citus to plan ahead and move shards the minimum number of times.

1. Run this for each node that you want to remove:

```
SELECT * FROM citus_set_node_property(node_hostname, node_port,
  'shouldhaveshards', false);
```

2. Drain them all at once with the [citus\\_rebalance\\_start](#) function:

```
SELECT * FROM citus_rebalance_start(drain_only := true);
```

3. Wait until the draining rebalance finishes.

4. Remove the nodes.

```
isolate_tenant_to_new_shard (table_name regclass, tenant_id "any", cascade_option text,
shard_transfer_mode citus.shard_transfer_mode) returns bigint
```

Creates a new shard to hold rows with a specific single value in the distribution column. It is especially handy for the multi-tenant citus use case, where a large tenant can be placed alone on its own shard and ultimately its own physical node. To learn more, see the [Tenant Isolation](#) section. The function returns the unique ID assigned to the newly created shard.

Arguments:

- *table\_name* — the name of the table to get a new shard.
- *tenant\_id* — the value of the distribution column which will be assigned to the new shard.
- *cascade\_option*. When set to `CASCADE`, also isolates a shard from all tables in the current table's [co-locating tables](#).
- *shard\_transfer\_mode* — specify the method of replication, whether to use Postgres Pro logical replication or a cross-worker `COPY` command. The allowed values of this optional argument are:
  - *auto* — require replica identity if logical replication is possible, otherwise use legacy behaviour. This is the default value.
  - *force\_logical* — use logical replication even if the table does not have a replica identity. Any concurrent update/delete statements to the table will fail during replication.
  - *block\_writes* — use `COPY` (blocking writes) for tables lacking primary key or replica identity.

The example below shows how to create a new shard to hold the lineitems for tenant 135:

```
SELECT isolate_tenant_to_new_shard('lineitem', 135);
```

|                             |
|-----------------------------|
| isolate_tenant_to_new_shard |
| 102240                      |

`citus_create_restore_point (name text)` returns `pg_lsn`

Temporarily blocks writes to the cluster, and creates a named restore point on all nodes. This function is similar to [pg\\_create\\_restore\\_point](#), but applies to all nodes and makes sure the restore point is consistent across them. This function is well suited to doing point-in-time recovery, and cluster forking. The function returns the `coordinator_lsn` value, i.e. the log sequence number of the restore point in the coordinator node WAL.

Arguments:

- *name* — the name of the restore point to create.

The example below shows how to use the function:

```
SELECT citus_create_restore_point('foo');
```

|                            |
|----------------------------|
| citus_create_restore_point |
| 0/1EA2808                  |

### J.5.7.5.2. citus Tables and Views

#### J.5.7.5.2.1. Coordinator Metadata

`citus` divides each distributed table into multiple logical shards based on the distribution column. The coordinator then maintains metadata tables to track statistics and information about the health and location of these shards. In this section, we describe each of these metadata tables and their schema. You can view and query these tables using SQL after logging into the coordinator node.

##### The `pg_dist_partition` Table

The `pg_dist_partition` table stores metadata about which tables in the database are distributed. For each distributed table, it also stores information about the distribution method and detailed information about the distribution column.

| Name         | Type     | Description                                                                                                                                                                                                                                                   |
|--------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| logicalrelid | regclass | Distributed table to which this row corresponds. This value references the <code>relfilenode</code> column in the <a href="#">pg_class</a> system catalog table.                                                                                              |
| partmethod   | char     | The method used for partitioning / distribution. The values of this column corresponding to different distribution methods are: hash — <i>h</i> , reference table — <i>n</i> .                                                                                |
| partkey      | text     | Detailed information about the distribution column including column number, type, and other relevant information.                                                                                                                                             |
| colocationid | integer  | Co-location group to which this table belongs. Tables in the same group allow co-located joins and distributed rollups among other optimizations. This value references the <code>colocationid</code> column in the <a href="#">pg_dist_colocation</a> table. |
| repmodel     | char     | The method used for data replication. The values of this column corresponding to different replication methods are: Postgres Pro streaming replication — <i>s</i> , two-phase commit (for reference tables) — <i>t</i> .                                      |

```

SELECT * FROM pg_dist_partition;
 logicalrelid | partmethod |
      partkey                               | colocationid |
      repmodel

### The pg\_dist\_shard Table

The `pg_dist_shard` table stores metadata about individual shards of a table. This includes information about which distributed table the shard belongs to and statistics about the distribution column for that shard. In case of hash distributed tables, they are hash token ranges assigned to that shard. These statistics are used for pruning away unrelated shards during `SELECT` queries.

| Name          | Type     | Description                                                                                                                                                 |
|---------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| logicalrelid  | regclass | Distributed table to which this shard belongs. This value references the <code>relfilenode</code> column in the <code>pg_class</code> system catalog table. |
| shardid       | bigint   | Globally unique identifier assigned to this shard.                                                                                                          |
| shardstorage  | char     | Type of storage used for this shard. Different storage types are discussed in the table below.                                                              |
| shardminvalue | text     | For hash distributed tables, minimum hash token value assigned to that shard (inclusive).                                                                   |
| shardmaxvalue | text     | For hash distributed tables, maximum hash token value assigned to that shard (inclusive).                                                                   |

```

SELECT * FROM pg_dist_shard;
 logicalrelid | shardid | shardstorage | shardminvalue | shardmaxvalue
-----+-----+-----+-----+-----
github_events | 102026 | t           | 268435456     | 402653183
github_events | 102027 | t           | 402653184     | 536870911
github_events | 102028 | t           | 536870912     | 671088639
github_events | 102029 | t           | 671088640     | 805306367
(4 rows)

```

The `shardstorage` column in `pg_dist_shard` indicates the type of storage used for the shard. A brief overview of different shard storage types and their representation is below.

| Storage Type | shardstorage value | Description                                                                                      |
|--------------|--------------------|--------------------------------------------------------------------------------------------------|
| TABLE        | t                  | Indicates that shard stores data belonging to a regular distributed table.                       |
| COLUMNAR     | c                  | Indicates that shard stores columnar data. (Used by distributed <code>cstore_fdw</code> tables). |
| FOREIGN      | f                  | Indicates that shard stores foreign data. (Used by distributed <code>file_fdw</code> tables).    |

### The citus\_shards View

In addition to the low-level shard metadata table described above, citus provides the `citus_shards` view to easily check:

- Where each shard is (node and port),
- What kind of table it belongs to, and
- Its size.

This view helps you inspect shards to find, among other things, any size imbalances across nodes.

```
SELECT * FROM citus_shards;
```

```
.
table_name | shardid | shard_name | citus_table_type | colocation_id | nodename |
nodeport | shard_size
-----+-----+-----+-----+-----+-----+
+-----+-----+
dist       | 102170 | dist_102170 | distributed      | 34 | localhost |
9701 | 90677248
dist       | 102171 | dist_102171 | distributed      | 34 | localhost |

dist2      | 102178 | dist2_102178 | distributed      | 34 | localhost |
9702 | 933888
```

The `colocation_id` refers to the [colocation group](#). For more info about `citus_table_type`, see the [Table Types](#) section.

#### The `pg_dist_placement` Table

The `pg_dist_placement` table tracks the location of shards on worker nodes. Each shard assigned to a specific node is called a shard placement. This table stores information about the health and location of each shard placement.

| Name        | Type   | Description                                                                                                                                                |
|-------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| placementid | bigint | Unique auto-generated identifier for each individual placement.                                                                                            |
| shardid     | bigint | Shard identifier associated with this placement. This value references the <code>shardid</code> column in the <a href="#">pg_dist_shard</a> catalog table. |
| shardstate  | int    | Describes the state of this placement. Different shard states are discussed in the section below.                                                          |
| shardlength | bigint | For hash distributed tables, zero.                                                                                                                         |
| groupid     | int    | Identifier used to denote a group of one primary server and zero or more secondary servers.                                                                |

```
SELECT * FROM pg_dist_placement;
```

```
placementid | shardid | shardstate | shardlength | groupid
-----+-----+-----+-----+-----
1 | 102008 | 1 | 0 | 1
2 | 102008 | 1 | 0 | 2
3 | 102009 | 1 | 0 | 2
```

|   |        |   |   |   |
|---|--------|---|---|---|
| 4 | 102009 | 1 | 0 | 3 |
| 5 | 102010 | 1 | 0 | 3 |
| 6 | 102010 | 1 | 0 | 4 |
| 7 | 102011 | 1 | 0 | 4 |

**The pg\_dist\_node Table**

The `pg_dist_node` table contains information about the worker nodes in the cluster.

| Name              | Type    | Description                                                                                                                                                                                  |
|-------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nodeid            | int     | Auto-generated identifier for an individual node.                                                                                                                                            |
| groupid           | int     | Identifier used to denote a group of one primary server and zero or more secondary servers. By default it is the same as the <code>nodeid</code> .                                           |
| nodename          | text    | Host name or IP Address of the Postgres Pro worker node.                                                                                                                                     |
| nodeport          | int     | Port number on which the Postgres Pro worker node is listening.                                                                                                                              |
| noderack          | text    | Rack placement information for the worker node. This is an optional column.                                                                                                                  |
| hasmetadata       | boolean | Reserved for internal use.                                                                                                                                                                   |
| isactive          | boolean | Whether the node is active accepting shard placements.                                                                                                                                       |
| noderole          | text    | Whether the node is a primary or secondary.                                                                                                                                                  |
| nodecluster       | text    | The name of the cluster containing this node.                                                                                                                                                |
| metadata-synced   | boolean | Reserved for internal use.                                                                                                                                                                   |
| shouldhave-shards | boolean | If false, shards will be moved off node (drained) when rebalancing, nor will shards from new distributed tables be placed on the node, unless they are co-located with shards already there. |

```
SELECT * FROM pg_dist_node;
 nodeid | groupid | nodename | nodeport | noderack | hasmetadata | isactive | noderole
-----+-----+-----+-----+-----+-----+-----+-----
 1 | 1 | localhost | 12345 | default | f | t | primary
 | default | f | t
 2 | 2 | localhost | 12346 | default | f | t | primary
 | default | f | t
 3 | 3 | localhost | 12347 | default | f | t | primary
 | default | f | t
(3 rows)
```

**The citus.pg\_dist\_object Table**

The `citus.pg_dist_object` table contains a list of objects such as types and functions that have been created on the coordinator node and propagated to worker nodes. When an administrator adds new worker nodes to the cluster, citus automatically creates copies of the distributed objects on the new nodes (in the correct order to satisfy object dependencies).

| Name     | Type    | Description                                                                     |
|----------|---------|---------------------------------------------------------------------------------|
| classid  | oid     | Class of the distributed object                                                 |
| objid    | oid     | Object ID of the distributed object                                             |
| objsubid | integer | Object sub-ID of the distributed object, e.g. <code>attnum</code>               |
| type     | text    | Part of the stable address used during upgrades with <a href="#">pg_upgrade</a> |

| Name                        | Type    | Description                                                                     |
|-----------------------------|---------|---------------------------------------------------------------------------------|
| object_names                | text[]  | Part of the stable address used during upgrades with <a href="#">pg_upgrade</a> |
| object_args                 | text[]  | Part of the stable address used during upgrades with <a href="#">pg_upgrade</a> |
| distribution_argument_index | integer | Only valid for distributed functions/procedures                                 |
| colocationid                | integer | Only valid for distributed functions/procedures                                 |

“Stable addresses” uniquely identify objects independently of a specific server. citus tracks objects during a Postgres Pro upgrade using stable addresses created with the [pg\\_identify\\_object\\_as\\_address](#) function.

Here is an example of how the [create\\_distributed\\_function](#) function adds entries to the `citus.pg_dist_object` table:

```
CREATE TYPE stoplight AS enum ('green', 'yellow', 'red');

CREATE OR REPLACE FUNCTION intersection()
RETURNS stoplight AS $$
DECLARE
    color stoplight;
BEGIN
    SELECT *
        FROM unnest(enum_range(NULL::stoplight)) INTO color
        ORDER BY random() LIMIT 1;
    RETURN color;
END;
$$ LANGUAGE plpgsql VOLATILE;

SELECT create_distributed_function('intersection()');

#### The `citus_schemas` View

citus supports [schema-based sharding](#) and provides the `citus_schemas` view that shows which schemas have been distributed in the system. The view only lists distributed schemas, local schemas are not displayed.

| Name          | Type          | Description                                                  |
|---------------|---------------|--------------------------------------------------------------|
| schema_name   | regname-space | Name of the distributed schema                               |
| colocation_id | integer       | Co-location ID of the distributed schema                     |
| schema_size   | text          | Human-readable size summary of all objects within the schema |
| schema_owner  | name          | Role that owns the schema                                    |

Here is an example:

```

schema_name | colocation_id | schema_size | schema_owner
-----+-----+-----+-----
user_service |          1 | 0 bytes | user_service
time_service |          2 | 0 bytes | time_service
ping_service |          3 | 632 kB | ping_service

```

#### The citus\_tables View

The `citus_tables` view shows a summary of all tables managed by citus (distributed and reference tables). The view combines information from citus metadata tables for an easy, human-readable overview of these table properties:

- [Table type](#)
- [Distribution column](#)
- [Co-location group ID](#)
- Human-readable size
- Shard count
- Owner (database user)
- Access method (heap or [columnar](#))

Here is an example:

```
SELECT * FROM citus_tables;
```

| table_name  | citus_table_type | distribution_column | colocation_id | table_size |  |
|-------------|------------------|---------------------|---------------|------------|--|
| shard_count | table_owner      | access_method       |               |            |  |
| foo.test    | distributed      | test_column         | 1             | 0 bytes    |  |
| 32          | citus            | heap                |               |            |  |
| ref         | reference        | <none>              | 2             | 24 GB      |  |
| 1           | citus            | heap                |               |            |  |
| test        | distributed      | id                  | 1             | 248 TB     |  |
| 32          | citus            | heap                |               |            |  |

#### The time\_partitions View

citus provides user defined functions to manage partitions for the [timeseries](#) use case. It also maintains the `time_partitions` view to inspect the partitions it manages.

The columns of this view are as follows:

- `parent_table` — the table which is partitioned.
- `partition_column` — the column on which the parent table is partitioned.
- `partition` — the name of a partition.
- `from_value` — lower bound in time for rows in this partition.
- `to_value` — upper bound in time for rows in this partition.
- `access_method` — heap for row-based storage and `columnar` for columnar storage.

```
SELECT * FROM time_partitions;
```

| parent_table<br>from_value                    | partition_column<br>to_value      | access_method                                       | partition |
|-----------------------------------------------|-----------------------------------|-----------------------------------------------------|-----------|
| github_columnar_events<br>2015-01-01 00:00:00 | created_at<br>2015-01-01 02:00:00 | github_columnar_events_p2015_01_01_0000<br>columnar |           |
| github_columnar_events<br>2015-01-01 02:00:00 | created_at<br>2015-01-01 04:00:00 | github_columnar_events_p2015_01_01_0200<br>columnar |           |
| github_columnar_events<br>2015-01-01 04:00:00 | created_at<br>2015-01-01 06:00:00 | github_columnar_events_p2015_01_01_0400<br>columnar |           |
| github_columnar_events<br>2015-01-01 06:00:00 | created_at<br>2015-01-01 08:00:00 | github_columnar_events_p2015_01_01_0600<br>heap     |           |

#### The pg\_dist\_colocation Table

The `pg_dist_colocation` table contains information about which tables' shards should be placed together, or [co-located](#). When two tables are in the same co-location group, citus ensures shards with the same partition values will be placed on the same worker nodes. This enables join optimizations, certain distributed rollups, and foreign key support. Shard co-location is inferred when the shard counts, and partition column types all match between two tables; however, a custom co-location group may be specified when creating a distributed table, if so desired.

| Name                         | Type | Description                                                                       |
|------------------------------|------|-----------------------------------------------------------------------------------|
| colocationid                 | int  | Unique identifier for the co-location group this row corresponds to               |
| shardcount                   | int  | Shard count for all tables in this co-location group                              |
| replicationfactor            | int  | Replication factor for all tables in this co-location group. (Deprecated)         |
| distributioncolumnstype      | oid  | The type of the distribution column for all tables in this co-location group      |
| distributioncolumnscollation | oid  | The collation of the distribution column for all tables in this co-location group |

```
SELECT * FROM pg_dist_colocation;
 colocationid | shardcount | replicationfactor | distributioncolumnstype |
distributioncolumnscollation
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
                2 |          32 |              1 |                20 |
                0
(1 row)
```

#### The pg\_dist\_rebalance\_strategy Table

This table defines strategies that the `citus_rebalance_start` function can use to determine where to move shards.

| Name                | Type    | Description                                                                                                                                                     |
|---------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name                | name    | Unique name for the strategy                                                                                                                                    |
| default_strategy    | boolean | Whether <code>citus_rebalance_start</code> should choose this strategy by default. Use <code>citus_set_default_rebalance_strategy</code> to update this column. |
| shard_cost_function | regproc | Identifier for a cost function, which must take a <code>shardid</code> as <code>bigint</code> and return its notion of a cost, as type <code>real</code> .      |

| Name                           | Type    | Description                                                                                                                                                                                                                                                              |
|--------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| node_capacity_function         | regproc | Identifier for a capacity function, which must take a <code>nodeid</code> as <code>int</code> and return its notion of node capacity as <code>type real</code> .                                                                                                         |
| shard_allowed_on_node_function | regproc | Identifier for a function that given <code>shardid</code> <code>bigint</code> and <code>nodeidarg</code> <code>int</code> , returns <code>boolean</code> for whether the shard is allowed to be stored on the node.                                                      |
| default_threshold              | float4  | Threshold for deeming a node too full or too empty, which determines when the <a href="#">citus_rebalance_start</a> function should try to move shards.                                                                                                                  |
| minimum_threshold              | float4  | A safeguard to prevent the threshold argument of <a href="#">citus_rebalance_start</a> from being set too low.                                                                                                                                                           |
| improvement_threshold          | float4  | Determines when moving a shard is worth it during a rebalance. The rebalancer will move a shard when the ratio of the improvement with the shard move to the improvement without crosses the threshold. This is most useful with the <code>by_disk_size</code> strategy. |

A citus installation ships with these strategies in the table:

```
SELECT * FROM pg_dist_rebalance_strategy;
```

```

-[ RECORD 1 ]-----+-----
name                | by_shard_count
default_strategy     | f
shard_cost_function  | citus_shard_cost_1
node_capacity_function | citus_node_capacity_1
shard_allowed_on_node_function | citus_shard_allowed_on_node_true
default_threshold    | 0
minimum_threshold    | 0
improvement_threshold | 0
-[ RECORD 2 ]-----+-----
name                | by_disk_size
default_strategy     | t
shard_cost_function  | citus_shard_cost_by_disk_size
node_capacity_function | citus_node_capacity_1
shard_allowed_on_node_function | citus_shard_allowed_on_node_true
default_threshold    | 0.1
minimum_threshold    | 0.01
improvement_threshold | 0.5

```

The `by_disk_size` strategy assigns every shard the same cost. Its effect is to equalize the shard count across nodes. The default strategy, `by_shard_count`, assigns a cost to each shard matching its disk size in bytes plus that of the shards that are co-located with it. The disk size is calculated using [pg\\_total\\_relation\\_size](#), so it includes indices. This strategy attempts to achieve the same disk space on every node. Note the threshold of 0.1 — it prevents unnecessary shard movement caused by insignificant differences in disk space.

Here are examples of functions that can be used within new shard rebalancer strategies, and registered in the `pg_dist_rebalance_strategy` table with the [citus\\_add\\_rebalance\\_strategy](#) function.

- Setting a node capacity exception by hostname pattern:

```
-- Example of node_capacity_function

CREATE FUNCTION v2_node_double_capacity(nodeidarg int)
RETURNS real AS $$
```

```
SELECT
  (CASE WHEN nodename LIKE '%.v2.worker.citusdata.com' THEN 2.0::float4 ELSE
1.0::float4 END)
FROM pg_dist_node where nodeid = nodeidarg
$$ LANGUAGE sql;
```

- Rebalancing by number of queries that go to a shard, as measured by the [citus\\_stat\\_statements](#) table:

```
-- Example of shard_cost_function
```

```
CREATE FUNCTION cost_of_shard_by_number_of_queries(shardid bigint)
  RETURNS real AS $$
  SELECT coalesce(sum(calls)::real, 0.001) as shard_total_queries
  FROM citus_stat_statements
  WHERE partition_key is not null
    AND get_shard_id_for_distribution_column('tab', partition_key) = shardid;
$$ LANGUAGE sql;
```

- Isolating a specific shard (10000) on a node (address '10.0.0.1'):

```
-- Example of shard_allowed_on_node_function
```

```
CREATE FUNCTION isolate_shard_10000_on_10_0_0_1(shardid bigint, nodeidarg int)
  RETURNS boolean AS $$
  SELECT
    (CASE WHEN nodename = '10.0.0.1' THEN shardid = 10000 ELSE shardid != 10000
END)
FROM pg_dist_node where nodeid = nodeidarg
$$ LANGUAGE sql;
```

```
-- The next two definitions are recommended in combination with the above function.
-- This way the average utilization of nodes is not impacted by the isolated shard
```

```
CREATE FUNCTION no_capacity_for_10_0_0_1(nodeidarg int)
  RETURNS real AS $$
  SELECT
    (CASE WHEN nodename = '10.0.0.1' THEN 0 ELSE 1 END)::real
  FROM pg_dist_node where nodeid = nodeidarg
  $$ LANGUAGE sql;
CREATE FUNCTION no_cost_for_10000(shardid bigint)
  RETURNS real AS $$
  SELECT
    (CASE WHEN shardid = 10000 THEN 0 ELSE 1 END)::real
  $$ LANGUAGE sql;
```

#### The citus\_stat\_statements Table

citus provides the `citus_stat_statements` table for stats about how queries are being executed, and for whom. It is analogous to (and can be joined with) the [pg\\_stat\\_statements](#) view in Postgres Pro, which tracks statistics about query speed.

| Name          | Type   | Description                                                        |
|---------------|--------|--------------------------------------------------------------------|
| queryid       | bigint | Identifier (good for <code>pg_stat_statements</code> joins)        |
| userid        | oid    | User who ran the query                                             |
| dbid          | oid    | Database instance of coordinator                                   |
| query         | text   | Anonymized query string                                            |
| executor      | text   | citus <a href="#">executor</a> used: adaptive, or INSERT-SELECT    |
| partition_key | text   | Value of distribution column in router-executed queries, else NULL |

| Name  | Type   | Description                       |
|-------|--------|-----------------------------------|
| calls | bigint | Number of times the query was run |

```
-- Create and populate distributed table
CREATE TABLE foo ( id int );
SELECT create_distributed_table('foo', 'id');
INSERT INTO foo select generate_series(1,100);

-- Enable stats
-- pg_stat_statements must be in shared_preload_libraries
CREATE EXTENSION pg_stat_statements;

SELECT count(*) from foo;
SELECT * FROM foo where id = 42;

SELECT * FROM citus_stat_statements;
```

**Results:**

```
-[ RECORD 1 ]-+-----
queryid      | -909556869173432820
userid       | 10
dbid         | 13340
query        | insert into foo select generate_series($1,$2)
executor     | insert-select
partition_key |
calls        | 1
-[ RECORD 2 ]-+-----
queryid      | 3919808845681956665
userid       | 10
dbid         | 13340
query        | select count(*) from foo;
executor     | adaptive
partition_key |
calls        | 1
-[ RECORD 3 ]-+-----
queryid      | 5351346905785208738
userid       | 10
dbid         | 13340
query        | select * from foo where id = $1
executor     | adaptive
partition_key | 42
calls        | 1
```

**Caveats:**

- The stats data is not replicated and will not survive database crashes or failover.
- Tracks a limited number of queries set by the [pg\\_stat\\_statements.max](#) configuration parameter. The default value is 5000.
- To truncate the table, use the [citus\\_stat\\_statements\\_reset](#) function.

**The citus\_stat\_tenants View**

The `citus_stat_tenants` view augments the [citus\\_stat\\_statements](#) table with information about how many queries each tenant is running. Tracing queries to originating tenants helps, among other things, for deciding when to do [tenant isolation](#).

This view counts recent single-tenant queries happening during a configurable time period. The tally of read-only and total queries for the period increases until the current period ends. After that, the counts

are moved to last period's statistics, which stays constant until expiration. The period length can be set in seconds using `citus.stats_tenants_period`, and is 60 seconds by default.

The view displays up to `citus.stat_tenants_limit` rows (by default 100). It counts only queries filtered to a single tenant, ignoring queries that apply to multiple tenants at once.

| Name                                    | Type   | Description                                                         |
|-----------------------------------------|--------|---------------------------------------------------------------------|
| <code>nodeid</code>                     | int    | Node ID from the <a href="#">pg_dist_node</a>                       |
| <code>colocation_id</code>              | int    | ID of the <a href="#">co-location group</a>                         |
| <code>tenant_attribute</code>           | text   | Value in the distribution column identifying tenant                 |
| <code>read_count_in_this_period</code>  | int    | Number of read ( <code>SELECT</code> ) queries for tenant in period |
| <code>read_count_in_last_period</code>  | int    | Number of read queries one period of time ago                       |
| <code>query_count_in_this_period</code> | int    | Number of read/write queries for tenant in time period              |
| <code>query_count_in_last_period</code> | int    | Number of read/write queries one period of time ago                 |
| <code>cpu_usage_in_this_period</code>   | double | Seconds of CPU time spent for this tenant in period                 |
| <code>cpu_usage_in_last_period</code>   | double | Seconds of CPU time spent for this tenant last period               |

Tracking tenant level statistics adds overhead, and by default is disabled. To enable it, set `citus.stat_tenants_track` to 'all'.

By way of example, suppose we have a distributed table called `dist_table`, with distribution column `tenant_id`. Then we make some queries:

```
INSERT INTO dist_table(tenant_id) VALUES (1);
INSERT INTO dist_table(tenant_id) VALUES (1);
INSERT INTO dist_table(tenant_id) VALUES (2);
```

```
SELECT count(*) FROM dist_table WHERE tenant_id = 1;
```

The tenant-level statistics will reflect the queries we just made:

```
SELECT tenant_attribute, read_count_in_this_period,
       query_count_in_this_period, cpu_usage_in_this_period
FROM citus_stat_tenants;
```

```
tenant_attribute | read_count_in_this_period | query_count_in_this_period |
cpu_usage_in_this_period
-----+-----+-----+
1                | 2                         | 2                         |
0.000883
2                | 0                         | 1                         |
0.000144
```

### Distributed Query Activity

In some situations, queries might get blocked on row-level locks on one of the shards on a worker node. If that happens then those queries would not show up in [pg\\_locks](#) on the citus coordinator node.

`citus` provides special views to watch queries and locks throughout the cluster, including shard-specific queries used internally to build results for distributed queries.

- `citus_stat_activity` — shows the distributed queries that are executing on all nodes. A superset of [pg\\_stat\\_activity](#) usable wherever the latter is.
- `citus_dist_stat_activity` — the same as `citus_stat_activity` but restricted to distributed queries only, and excluding citus fragments queries.
- `citus_lock_waits` — blocked queries throughout the cluster.

The first two views include all columns of `pg_stat_activity` plus the global PID of the worker that initiated the query.

For example, consider counting the rows in a distributed table:

```
-- Run in one session
-- (with a pg_sleep so we can see it)
```

```
SELECT count(*), pg_sleep(3) FROM users_table;
```

We can see the query appear in `citus_dist_stat_activity`:

```
-- Run in another session
```

```
SELECT * FROM citus_dist_stat_activity;
```

```
-[ RECORD 1 ]-----+-----
global_pid      | 10000012199

```

The `citus_dist_stat_activity` view hides internal citus fragment queries. To see those, we can use the more detailed `citus_stat_activity` view. For instance, the previous `count(*)` query requires information from all shards. Some of the information is in shard `users_table_102039`, which is visible in the query below.

```
SELECT * FROM citus_stat_activity;
```

```
-[ RECORD 1 ]-----+-----

xact_start        |
query_start       | 2022-03-23 19:32:18.278121-05
state_change      | 2022-03-23 19:32:18.278281-05
wait_event_type   | Client
wait_event        | ClientRead
state             | idle
backend_xid       |
backend_xmin      |
query_id          |
query             | SELECT count(*) AS count FROM public.users_table_102039 users WHERE
true
backend_type      | client backend

```

The query field shows rows being counted in shard 102039.

Here are examples of useful queries you can build using `citus_stat_activity`:

```
-- Active queries' wait events
```

```
SELECT query, wait_event_type, wait_event
FROM citus_stat_activity
WHERE state='active';
```

```
-- Active queries' top wait events
```

```
SELECT wait_event, wait_event_type, count(*)
```

```
FROM citus_stat_activity
WHERE state='active'
GROUP BY wait_event, wait_event_type
ORDER BY count(*) desc;

-- Total internal connections generated per node by citus
```

```
SELECT nodeid, count(*)
FROM citus_stat_activity
WHERE is_worker_query
GROUP BY nodeid;
```

The next view is `citus_lock_waits`. To see how it works, we can generate a locking situation manually. First we will set up a test table from the coordinator:

```
CREATE TABLE numbers AS
SELECT i, 0 AS j FROM generate_series(1,10) AS i;
SELECT create_distributed_table('numbers', 'i');
```

Then, using two sessions on the coordinator, we can run this sequence of statements:

```
-- Session 1                                -- Session 2
-----
BEGIN;
UPDATE numbers SET j = 2 WHERE i = 1;
                                BEGIN;
                                UPDATE numbers SET j = 3 WHERE i = 1;
                                -- (this blocks)
```

The `citus_lock_waits` view shows the situation.

```
SELECT * FROM citus_lock_waits;

-[ RECORD 1 ]-----+-----
waiting_gpid        | 10000011981
blocking_gpid       | 10000011979
blocked_statement   | UPDATE numbers SET j = 3 WHERE i = 1;
current_statement_in_blocking_process | UPDATE numbers SET j = 2 WHERE i = 1;
waiting_nodeid      | 1
blocking_nodeid     | 1
```

In this example the queries originated on the coordinator, but the view can also list locks between queries originating on workers.

#### J.5.7.5.2.2. Tables on All Nodes

`citus` has other informational tables and views which are accessible on all nodes, not just the coordinator.

##### The `pg_dist_authinfo` Table

The `pg_dist_authinfo` table holds authentication parameters used by `citus` nodes to connect to one another.

| Name     | Type    | Description                                             |
|----------|---------|---------------------------------------------------------|
| nodeid   | integer | Node ID from <a href="#">pg_dist_node</a> , or 0, or -1 |
| rolename | name    | Postgres Pro role                                       |
| authinfo | text    | Space-separated libpq connection parameters             |

Upon beginning a connection, a node consults the table to see whether a row with the destination `nodeid` and desired `rolename` exists. If so, the node includes the corresponding `authinfo` string in its libpq connection. A common example is to store a password, like `'password=abc123'`, but you can review the [full list](#) of possibilities.

The parameters in `authinfo` are space-separated, in the form `key=val`. To write an empty value, or a value containing spaces, surround it with single quotes, e.g., `keyword='a value'`. Single quotes and backslashes within the value must be escaped with a backslash, i.e., `\'` and `\\`.

The `nodeid` column can also take the special values 0 and -1, which mean *all nodes* or *loopback connections*, respectively. If, for a given node, both specific and all-node rules exist, the specific rule has precedence.

```
SELECT * FROM pg_dist_authinfo;

 nodeid | rolename | authinfo
-----+-----+-----
    123 | jdoe     | password=abc123
(1 row)
```

#### The `pg_dist_poolinfo` Table

If you want to use a connection pooler to connect to a node, you can specify the pooler options using `pg_dist_poolinfo`. This metadata table holds the host, port and database name for citus to use when connecting to a node through a pooler.

If pool information is present, citus will try to use these values instead of setting up a direct connection. The `pg_dist_poolinfo` information in this case supersedes [pg\\_dist\\_node](#).

| Name     | Type    | Description                                       |
|----------|---------|---------------------------------------------------|
| nodeid   | integer | Node ID from <a href="#">pg_dist_node</a>         |
| poolinfo | text    | Space-separated parameters: host, port, or dbname |

### Note

In some situations citus ignores the settings in `pg_dist_poolinfo`. For instance [shard rebalancing](#) is not compatible with connection poolers such as [pgbouncer](#). In these scenarios citus will use a direct connection.

```
-- How to connect to node 1 (as identified in pg_dist_node)
```

```
INSERT INTO pg_dist_poolinfo (nodeid, poolinfo)
VALUES (1, 'host=127.0.0.1 port=5433');
```

#### J.5.7.5.3. Configuration Reference

There are various configuration parameters that affect the behaviour of citus. These include both standard Postgres Pro parameters and citus specific parameters. To learn more about Postgres Pro configuration parameters, you can visit the [Server Configuration](#) chapter.

The rest of this reference aims at discussing citus specific configuration parameters. These parameters can be set similar to Postgres Pro parameters by modifying `postgresql.conf` or [by using the SET command](#).

As an example you can update a setting with:

```
ALTER DATABASE citus SET citus.multi_task_query_log_level = 'log';
```

##### J.5.7.5.3.1. General Configuration

```
citus.max_background_task_executors_per_node (integer)
```

Determines how many background tasks can be executed in parallel at a given time. For instance, these tasks are for shard moves from/to a node. When increasing the value of this parameter, you will

often also want to increase the value of the `citus.max_background_task_executors` and `max_worker_processes` parameters. The minimum value is 1, the maximum value is 128. The default value is 1.

`citus.max_worker_nodes_tracked` (integer)

`citus` tracks worker nodes' locations and their membership in a shared hash table on the coordinator node. This configuration parameter limits the size of the hash table and consequently the number of worker nodes that can be tracked. The default value is 2048. This parameter can only be set at server start and is effective on the coordinator node.

`citus.use_secondary_nodes` (enum)

Sets the policy to use when choosing nodes for the `SELECT` queries. If set to `always`, the planner will query only nodes whose `noderole` is marked as `secondary` in the `pg_dist_node` table. The allowed values are:

- `never` — all reads happen on primary nodes. This is the default value.
- `always` — reads run against secondary nodes instead and `INSERT/UPDATE` statements are disabled.

`citus.cluster_name` (text)

Informs the coordinator node planner which cluster it coordinates. Once `cluster_name` is set, the planner will query worker nodes in that cluster alone.

`citus.enable_version_checks` (boolean)

Upgrading `citus` version requires a server restart (to pick up the new shared library), as well as running the `ALTER EXTENSION UPDATE` command. The failure to execute both steps could potentially cause errors or crashes. `citus` thus validates the version of the code and that of the extension match, and errors out if they do not.

The default value is `true`, and the parameter is effective on the coordinator. In rare cases, complex upgrade processes may require setting this parameter to `false`, thus disabling the check.

`citus.log_distributed_deadlock_detection` (boolean)

Specifies whether to log distributed deadlock detection related processing in the server log. The default value is `false`.

`citus.distributed_deadlock_detection_factor` (floating point)

Sets the time to wait before checking for distributed deadlocks. In particular the time to wait will be this value multiplied by the value set in the Postgres Pro `deadlock_timeout` parameter. The default value is 2. The value of -1 disables distributed deadlock detection.

`citus.node_connection_timeout` (integer)

Sets the maximum duration to wait for connection establishment, in milliseconds. `citus` raises an error if the timeout elapses before at least one worker connection is established. This configuration parameter affects connections from the coordinator to workers and workers to each other. The minimum value is 10 milliseconds, the maximum value is 1 hour. The default value is 30 seconds.

The example below shows how to set this parameter:

```
-- Set to 60 seconds
ALTER DATABASE foo
SET citus.node_connection_timeout = 60000;
```

`citus.node_conninfo` (text)

Sets non-sensitive [libpq connection parameters](#) used for all inter-node connections.

The example below shows how to set this parameter:

```
-- key=value pairs separated by spaces.  
-- For example, ssl options:
```

```
ALTER DATABASE foo  
SET citus.node_conninfo =  
    'sslrootcert=/path/to/citus.crt sslmode=verify-full';
```

citus supports only a specific subset of the allowed options, namely:

- application\_name
- connect\_timeout
- gsslib (subject to the runtime presence of optional Postgres Pro features)
- keepalives
- keepalives\_count
- keepalives\_idle
- keepalives\_interval
- krbsrvname (subject to the runtime presence of optional Postgres Pro features)
- sslcompression
- sslcrl
- sslmode (defaults to require)
- sslrootcert
- tcp\_user\_timeout

The `citus.node_conninfo` configuration parameter takes effect only on newly opened connections. To force all connections to use the new settings, make sure to reload the Postgres Pro configuration:

```
SELECT pg_reload_conf();
```

`citus.local_hostname` (text)

citus nodes need occasionally to connect to themselves for systems operations. By default, they use the `localhost` address to refer to themselves, but this can cause problems. For instance, when a host requires `sslmode=verify-full` for incoming connections, adding `localhost` as an alternative hostname on the SSL certificate is not always desirable or even feasible.

The `citus.local_hostname` configuration parameter selects the hostname a node uses to connect to itself. The default value is `localhost`.

The example below shows how to set this parameter:

```
ALTER SYSTEM SET citus.local_hostname TO 'mynode.example.com';
```

`citus.show_shards_for_app_name_prefixes` (text)

By default, citus hides shards from the list of tables Postgres Pro gives to SQL clients. It does this because there are multiple shards per distributed table, and the shards can be distracting to the SQL client.

The `citus.show_shards_for_app_name_prefixes` configuration parameter allows shards to be displayed for selected clients that want to see them. The default value is `''`.

The example below shows how to set this parameter:

```
-- Show shards to psql only (hide in other clients, like pgAdmin)
```

```
SET citus.show_shards_for_app_name_prefixes TO 'psql';
```

```
-- Also accepts a comma-separated list
```

```
SET citus.show_shards_for_app_name_prefixes TO 'psql,pg_dump';
```

`citus.rebalancer_by_disk_size_base_cost` (integer)

When using the `by_disk_size` rebalance strategy each shard group will get this cost in bytes added to its actual disk size. This is used to avoid creating a bad balance when there is very little data in some of the shards. The assumption is that even empty shards have some cost, because of parallelism and because empty shard groups will likely grow in the future. The default value is 100 MB.

#### J.5.7.5.3.2. Query Statistics

`citus.stat_statements_purge_interval` (integer)

Sets the frequency at which the maintenance daemon removes records from the `citus_stat_statements` table that are unmatched in the `pg_stat_statements` view. This configuration parameter sets the time interval between purges in seconds, with the default value of 10. The value of 0 disables the purges. This parameter is effective on the coordinator and can be changed at runtime.

The example below shows how to set this parameter:

```
SET citus.stat_statements_purge_interval TO 5;
```

`citus.stat_statements_max` (integer)

The maximum number of rows to store in the `citus_stat_statements` table. The default value is 50000 and may be changed to any value in the range of 1000 - 10000000. Note that each row requires 140 bytes of storage, so setting `citus.stat_statements_max` to its maximum value of 10M would consume 1.4GB of memory.

Changing this configuration parameter will not take effect until Postgres Pro is restarted.

`citus.stat_statements_track` (enum)

Recording statistics for `citus_stat_statements` requires extra CPU resources. When the database is experiencing load, the administrator may wish to disable statement tracking. The `citus.stat_statements_track` configuration parameter can turn tracking on and off. The allowed values are:

- `all` — track all statements. This is the default value.
- `none` — disable tracking.

`citus.stat_tenants_untracked_sample_rate` (floating point)

Sampling rate for new tenants in the `citus_stat_tenants` view. The rate can be of range between 0.0 and 1.0. The default value is 1.0 meaning 100% of untracked tenant queries are sampled. Setting it to a lower value means that the already tracked tenants have 100% queries sampled, but tenants that are currently untracked are sampled only at the provided rate.

#### J.5.7.5.3.3. Data Loading

`citus.shard_count` (integer)

Sets the shard count for hash-partitioned tables and defaults to 32. This value is used by the `create_distributed_table` function when creating hash-partitioned tables. This parameter can be set at runtime and is effective on the coordinator.

`citus.metadata_sync_mode` (enum)

### Note

This configuration parameter requires superuser access to change.

This configuration parameter determines how citus synchronizes `metadata` across nodes. By default, citus updates all metadata in a single transaction for consistency. However, Postgres Pro has a hard memory limit related to cache invalidations, and citus metadata syncing for a large cluster can fail from memory exhaustion.

As a workaround, citus provides an optional nontransactional sync mode, which uses a series of smaller transactions. While this mode works in limited memory, there is a possibility of transactions failing and leaving metadata in an inconsistency state. To help with this potential problem, nontransactional metadata sync is designed as an idempotent action, so you can re-run it repeatedly if needed.

There allowed values for this configuration parameters are as follows:

- `transactional` — synchronize all metadata in a single transaction. This is the default value.
- `nontransactional` — synchronize metadata using multiple small transactions.

The example below shows how to set this parameter:

```
-- To add a new node and sync nontransactionally

SET citus.metadata_sync_mode TO 'nontransactional';
SELECT citus_add_node(<ip>, <port>);

-- To manually (re)sync

SET citus.metadata_sync_mode TO 'nontransactional';
SELECT start_metadata_sync_to_all_nodes();
```

We advise trying transactional mode first and switching to nontransactional only if a memory failure occurs.

#### J.5.7.5.3.4. Planner Configuration

`citus.local_table_join_policy` (enum)

Determines how citus moves data when doing a join between local and distributed tables. Customizing the join policy can help reduce the amount of data sent between worker nodes.

citus will send either the local or distributed tables to nodes as necessary to support the join. Copying table data is referred to as a “conversion”. If a local table is converted, then it will be sent to any workers that need its data to perform the join. If a distributed table is converted, then it will be collected in the coordinator to support the join. The citus planner will send only the necessary rows doing a conversion.

There are four modes available to express conversion preference:

- `auto` — citus will convert either all local or all distributed tables to support local and distributed table joins. citus decides which to convert using a heuristic. It will convert distributed tables if they are joined using a constant filter on a unique index (such as a primary key). This ensures less data gets moved between workers. This is the default value.
- `never` — citus will not allow joins between local and distributed tables.
- `prefer-local` — citus will prefer converting local tables to support local and distributed table joins.
- `prefer-distributed` — citus will prefer converting distributed tables to support local and distributed table joins. If the distributed tables are huge, using this option might result in moving lots of data between workers.

For example, assume `citus_table` is a distributed table distributed by the column `x`, and that `postgres_table` is a local table:

```
CREATE TABLE citus_table(x int primary key, y int);
SELECT create_distributed_table('citus_table', 'x');

CREATE TABLE postgres_table(x int, y int);

-- Even though the join is on primary key, there isn't a constant filter
-- hence postgres_table will be sent to worker nodes to support the join
SELECT * FROM citus_table JOIN postgres_table USING (x);
```

```
-- There is a constant filter on a primary key, hence the filtered row
-- from the distributed table will be pulled to coordinator to support the join
SELECT * FROM citus_table JOIN postgres_table USING (x) WHERE citus_table.x = 10;

SET citus.local_table_join_policy to 'prefer-distributed';
-- Since we prefer distributed tables, citus_table will be pulled to coordinator
-- to support the join. Note that citus_table can be huge
SELECT * FROM citus_table JOIN postgres_table USING (x);

SET citus.local_table_join_policy to 'prefer-local';
-- Even though there is a constant filter on primary key for citus_table
-- postgres_table will be sent to necessary workers because we are using 'prefer-
local'
SELECT * FROM citus_table JOIN postgres_table USING (x) WHERE citus_table.x = 10;
```

`citus.limit_clause_row_fetch_count` (integer)

Sets the number of rows to fetch per task for limit clause optimization. In some cases, `SELECT` queries with `LIMIT` clauses may need to fetch all rows from each task to generate results. In those cases, and where an approximation would produce meaningful results, this configuration parameter sets the number of rows to fetch from each shard. Limit approximations are disabled by default and this parameter is set to `-1`. This value can be set at runtime and is effective on the coordinator.

`citus.count_distinct_error_rate` (floating point)

`citus` can calculate `count(distinct)` approximates using the Postgres Pro hll extension. This configuration parameter sets the desired error rate when calculating `count(distinct)`: `0.0`, which is the default value, disables approximations for `count(distinct)`, and `1.0`, which provides no guarantees about the accuracy of results. We recommend setting this parameter to `0.005` for best results. This value can be set at runtime and is effective on the coordinator.

`citus.task_assignment_policy` (enum)

### Note

This configuration parameter is applicable for queries against [reference tables](#).

Sets the policy to use when assigning tasks to workers. The coordinator assigns tasks to workers based on shard locations. This configuration parameter specifies the policy to use when making these assignments. Currently, there are three possible task assignment policies, which can be used:

- `greedy` — aims at evenly distributing tasks across workers. This is the default value.
- `round-robin` — assigns tasks to workers in a round-robin fashion alternating between different replicas. This enables much better cluster utilization when the shard count for a table is low compared to the number of workers.
- `first-replica` — assigns tasks on the basis of the insertion order of placements (replicas) for the shards. In other words, the fragment query for a shard is simply assigned to the worker which has the first replica of that shard. This method allows you to have strong guarantees about which shards will be used on which nodes (i.e. stronger memory residency guarantees).

This configuration parameter can be set at runtime and is effective on the coordinator.

`citus.enable_non_colocated_router_query_pushdown` (boolean)

Enables router planner for the queries that reference non-co-located distributed tables.

Normally, router planner is only enabled for the queries that reference co-located distributed tables because it is not guaranteed to have the target shards always on the same node, e.g., after rebalancing the shards. For this reason, while enabling this flag allows some degree of optimization for

the queries that reference non-colocated distributed tables, it is not guaranteed that the same query will work after rebalancing the shards or altering the shard count of one of those distributed tables. The default value is `off`.

#### J.5.7.5.3.5. Intermediate Data Transfer

`citus.max_intermediate_result_size` (integer)

The maximum size in KB of intermediate results for CTEs that are unable to be pushed down to worker nodes for execution, and for complex subqueries. The default is 1 GB and a value of `-1` means no limit. Queries exceeding the limit will be canceled and produce an error message.

#### J.5.7.5.3.6. DDL

`citus.enable_ddl_propagation` (boolean)

Specifies whether to automatically propagate DDL changes from the coordinator to all workers. The default value is `true`. Because some schema changes require an access exclusive lock on tables and because the automatic propagation applies to all workers sequentially it can make a citus cluster temporarily less responsive. You may choose to disable this setting and propagate changes manually.

### Note

For a list of DDL propagation support, see the [Modifying Tables](#) section.

`citus.enable_local_reference_table_foreign_keys` (boolean)

Allows foreign keys to be created between reference and local tables. For the feature to work, the coordinator node must be registered with itself, using the [citus\\_add\\_node](#) function. The default value is `true`.

Note that foreign keys between reference tables and local tables come at a slight cost. When you create the foreign key, citus must add the plain table to its metadata and track it in the [pg\\_dist\\_partition](#) table. Local tables that are added to metadata inherit the same limitations as reference tables (see the [Creating and Modifying Distributed Objects \(DDL\)](#) and [SQL Support and Workarounds](#) sections).

If you drop the foreign keys, citus will automatically remove such local tables from metadata, which eliminates such limitations on those tables.

`citus.enable_change_data_capture` (boolean)

Causes citus to alter the wal2json and pgoutput logical decoders to work with distributed tables. Specifically, it rewrites the names of shards (e.g. `foo_102027`) in decoder output to the base names of the distributed tables (e.g. `foo`). It also avoids publishing duplicate events during tenant isolation and shard split/move/rebalance operations. The default value is `false`.

`citus.enable_schema_based_sharding` (boolean)

With the parameter set to `ON` all created schemas will be distributed by default. Distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas will be automatically converted to co-located distributed tables without a shard key. This parameter can be modified for individual sessions.

To learn how to use this configuration parameter, see the [Microservices](#) section.

#### J.5.7.5.3.7. Executor Configuration

`citus.all_modifications_commutative` (boolean)

citus enforces commutativity rules and acquires appropriate locks for modify operations in order to guarantee correctness of behavior. For example, it assumes that an `INSERT` statement commutes with another `INSERT` statement, but not with an `UPDATE` or `DELETE` statement. Similarly, it assumes that an `UPDATE` or `DELETE` statement does not commute with another `UPDATE` or `DELETE` statement. This means that `UPDATE` and `DELETE` statements require citus to acquire stronger locks.

If you have `UPDATE` statements that are commutative with your `INSERTs` or other `UPDATES`, then you can relax these commutativity assumptions by setting this parameter to `true`. When this parameter is set to `true`, all commands are considered commutative and claim a shared lock, which can improve overall throughput. This parameter can be set at runtime and is effective on the coordinator.

`citus.multi_task_query_log_level` (enum)

Sets a log-level for any query which generates more than one task (i.e. which hits more than one shard). This is useful during a multi-tenant application migration, as you can choose to error or warn for such queries, to find them and add the `tenant_id` filter to them. This parameter can be set at runtime and is effective on the coordinator. The default value for this parameter is `off`. The following values are supported:

- `off` — turns off logging any queries, which generate multiple tasks (i.e. span multiple shards).
- `debug` — logs statement at the `DEBUG` severity level.
- `log` — logs statement at the `LOG` severity level. The log line will include the SQL query that was run.
- `notice` — logs statement at the `NOTICE` severity level.
- `warning` — logs statement at the `WARNING` severity level.
- `error` — logs statement at the `ERROR` severity level.

Note that it may be useful to use `error` during development testing and a lower log-level like `log` during actual production deployment. Choosing `log` will cause multi-task queries to appear in the database logs with the query itself shown after `STATEMENT`.

```
LOG:  multi-task query about to be executed
```

```
HINT:  Queries are split to multiple tasks if they have to be split into several  
       queries on the workers.
```

```
STATEMENT:  SELECT * FROM foo;
```

`citus.propagate_set_commands` (enum)

Determines which `SET` commands are propagated from the coordinator to workers. The default value is `none`. The following values are supported:

- `none` — no `SET` commands are propagated.
- `local` — only `SET LOCAL` commands are propagated.

`citus.enable_repartition_joins` (boolean)

Ordinarily, attempting to perform [repartition joins](#) with the adaptive executor will fail with an error message. However, setting this configuration parameter to `true` allows citus to perform the join. The default value is `false`.

`citus.enable_repartitioned_insert_select` (boolean)

By default, an `INSERT INTO ... SELECT` statement that cannot be pushed down will attempt to repartition rows from the `SELECT` statement and transfer them between workers for insertion. However, if the target table has too many shards then repartitioning will probably not perform well. The overhead of processing the shard intervals when determining how to partition the results is too great. Repartitioning can be disabled manually by setting this configuration parameter to `false`.

`citus.enable_binary_protocol` (boolean)

Setting this parameter to `true` instructs the coordinator node to use Postgres Pro binary serialization format (when applicable) to transfer data with workers. Some column types do not support binary serialization.

Enabling this parameter is mostly useful when the workers must return large amounts of data. Examples are when a lot of rows are requested, the rows have many columns, or they use big types such as `hll` type from the `hll` extension.

The default value is `true`. When set to `false`, all results are encoded and transferred in text format.

`citus.max_shared_pool_size` (integer)

Specifies the maximum number of connections that the coordinator node, across all simultaneous sessions, is allowed to make per worker node. Postgres Pro must allocate fixed resources for every connection and this configuration parameter helps ease connection pressure on workers.

Without connection throttling, every multi-shard query creates connections on each worker proportional to the number of shards it accesses (in particular, up to `#shards/#workers`). Running dozens of multi-shard queries at once can easily hit worker nodes' [max\\_connections](#) limit, causing queries to fail.

By default, the value is automatically set equal to the coordinator's own `max_connections`, which is not guaranteed to match that of the workers (see the note below). The value `-1` disables throttling.

### Note

There are certain operations that do not obey this parameter, most importantly repartition joins. That is why it can be prudent to increase the `max_connections` on the workers a bit higher than `max_connections` on the coordinator. This gives extra space for connections required for repartition queries on the workers.

`citus.max_adaptive_executor_pool_size` (integer)

Whereas [citus.max\\_shared\\_pool\\_size](#) limits worker connections across all sessions, the `citus.max_adaptive_executor_pool_size` limits worker connections from just the *current* session. This parameter is useful for:

- Preventing a single backend from getting all the worker resources.
- Providing priority management: designate low priority sessions with low `citus.max_adaptive_executor_pool_size` value and high priority sessions with higher values.

The default value is 16.

`citus.executor_slow_start_interval` (integer)

Time to wait between opening connections to the same worker node, in milliseconds.

When the individual tasks of a multi-shard query take very little time, they can often be finished over a single (often already cached) connection. To avoid redundantly opening additional connections, the executor waits between connection attempts for the configured number of milliseconds. At the end of the interval, it increases the number of connections it is allowed to open next time.

For long queries (those taking `>500 ms`), slow start might add latency, but for short queries it is faster. The default value is 10 ms.

`citus.max_cached_conns_per_worker` (integer)

Each backend opens connections to the workers to query the shards. At the end of the transaction, the configured number of connections is kept open to speed up subsequent commands. Increasing this value will reduce the latency of multi-shard queries but will also increase overhead on the workers.

The default value is 1. A larger value such as 2 might be helpful for clusters that use a small number of concurrent sessions, but it's not wise to go much further (e.g. 16 would be too high).

`citus.force_max_query_parallelization` (boolean)

Simulates the deprecated and now nonexistent real-time executor. This is used to open as many connections as possible to maximize query parallelization.

When this configuration parameter is enabled, citus will force the adaptive executor to use as many connections as possible while executing a parallel distributed query. If not enabled, the executor

might choose to use fewer connections to optimize overall query execution throughput. Internally, setting this parameter to `true` will end up using one connection per task. The default value is `false`.

One place where this is useful is in a transaction whose first query is lightweight and requires few connections, while a subsequent query would benefit from more connections. `citus` decides how many connections to use in a transaction based on the first statement, which can throttle other queries unless we use the configuration parameter to provide a hint.

The example below shows how to set this parameter:

```
BEGIN;
-- Add this hint
SET citus.force_max_query_parallelization TO ON;

-- A lightweight query that doesn't require many connections
SELECT count(*) FROM table WHERE filter = x;

-- A query that benefits from more connections, and can obtain
-- them since we forced max parallelization above
SELECT ... very .. complex .. SQL;
COMMIT;
```

`citus.explain_all_tasks (boolean)`

By default, `citus` shows the output of a single arbitrary task when running the `EXPLAIN` command on a distributed query. In most cases, the `EXPLAIN` output will be similar across tasks. Occasionally, some of the tasks will be planned differently or have much higher execution times. In those cases, it can be useful to enable this parameter, after which the `EXPLAIN` output will include all tasks. This may cause the `EXPLAIN` to take longer.

`citus.explain_analyze_sort_method (enum)`

Determines the sort method of the tasks in the output of `EXPLAIN ANALYZE`. The following values are supported:

- `execution-time` — sort by execution time.
- `taskId` — sort by task ID.

## J.5.8. Administer

### J.5.8.1. Cluster Management

In this section, we discuss how you can add or remove nodes from your `citus` cluster and how you can deal with node failures.

#### Note

To make moving shards across nodes or re-replicating shards on failed nodes easier, `citus` supports fully online shard rebalancing. We discuss briefly the functions provided by the shard rebalancer when relevant in the sections below. You can learn more about these functions, their arguments, and usage in the [Cluster Management And Repair Functions](#) section.

#### J.5.8.1.1. Choosing Cluster Size

This section explores configuration settings for running a cluster in production.

##### J.5.8.1.1.1. Shard Count

Choosing the shard count for each distributed table is a balance between the flexibility of having more shards and the overhead for query planning and execution across them. If you decide to change the shard count of a table after distributing, you can use the [alter\\_distributed\\_table](#) function.

### Multi-Tenant SaaS Use Case

The optimal choice varies depending on your access patterns for the data. For instance, in the [multi-tenant SaaS database](#) use case we recommend choosing between 32 and 128 shards. For smaller workloads, say <100GB, you could start with 32 shards and for larger workloads you could choose 64 or 128 shards. This means that you have the leeway to scale from 32 to 128 worker machines.

### Real-Time Analytics Use Case

In the [real-time analytics](#) use case, shard count should be related to the total number of cores on the workers. To ensure maximum parallelism, you should create enough shards on each node such that there is at least one shard per CPU core. We typically recommend creating a high number of initial shards, e.g. 2x or 4x the number of current CPU cores. This allows for future scaling if you add more workers and CPU cores.

However, keep in mind that for each query Citus opens one database connection per shard, and these connections are limited. Be careful to keep the shard count small enough that distributed queries will not often have to wait for a connection. Put another way, the connections needed,  $(\text{max\_concurrent\_queries} * \text{shard\_count})$ , should generally not exceed the total connections possible in the system,  $(\text{number of workers} * \text{max\_connections per worker})$ .

#### J.5.8.1.2. Initial Hardware Size

The size of a cluster, in terms of number of nodes and their hardware capacity, is easy to change. However, you still need to choose an initial size for a new cluster. Here are some tips for a reasonable initial cluster size.

##### J.5.8.1.2.1. Multi-Tenant SaaS Use Case

For those migrating to Citus from an existing single-node database instance, we recommend choosing a cluster where the number of worker cores and RAM in total equals that of the original instance. In such scenarios we have seen 2-3x performance improvements because sharding improves resource utilization, allowing smaller indices, etc.

The coordinator node needs less memory than workers, so you can choose a compute-optimized machine for running the coordinator. The number of cores required depends on your existing workload (write/read throughput).

##### J.5.8.1.2.2. Real-Time Analytics Use Case

**Total cores:** when working data fits in RAM, you can expect a linear performance improvement on Citus proportional to the number of worker cores. To determine the right number of cores for your needs, consider the current latency for queries in your single-node database and the required latency in Citus. Divide current latency by desired latency, and round the result.

**Worker RAM:** the best case would be providing enough memory that the majority of the working set fits in memory. The type of queries your application uses affect memory requirements. You can run `EXPLAIN ANALYZE` on a query to determine how much memory it requires.

#### J.5.8.1.3. Scaling the Cluster

Citus logical sharding based architecture allows you to scale out your cluster without any downtime. This section describes how you can add more nodes to your Citus cluster in order to improve query performance / scalability.

##### J.5.8.1.3.1. Adding a Worker

Citus stores all the data for distributed tables on the worker nodes. Hence, if you want to scale out your cluster by adding more computing power, you can do so by adding a worker.

To add a new node to the cluster, you first need to add the DNS name or IP address of that node and port (on which Postgres Pro is running) in the [pg\\_dist\\_node](#) catalog table. You can do so using the [citus\\_add\\_node](#) function. Example:

```
SELECT * from citus_add_node('node-name', 5432);
```

The new node is available for shards of new distributed tables. Existing shards will stay where they are unless redistributed, so adding a new worker may not help performance without further steps.

### Note

Also, new nodes synchronize citus [metadata](#) upon creation. By default, the sync happens inside a single transaction for consistency. However, in a big cluster with large amounts of metadata, the transaction can run out of memory and fail. If you encounter this situation, you can choose a non-transactional metadata sync mode with the [citus.metadata\\_sync\\_mode](#) configuration parameter.

#### J.5.8.1.3.2. Rebalancing Shards Without Downtime

If you want to move existing shards to a newly added worker, citus provides the [citus\\_rebalance\\_start](#) function to make it easier. This function will distribute shards evenly among the workers.

The function is configurable to rebalance shards according to a number of strategies, to best match your database workload. See the [function reference](#) to learn which strategy to choose. Here is an example of rebalancing shards using the default strategy:

```
SELECT citus_rebalance_start();
```

Many products like multi-tenant SaaS applications cannot tolerate downtime, and rebalancing is able to honor this requirement. This means reads and writes from the application can continue with minimal interruption while data is being moved.

#### Parallel Rebalancing

This operation carries out multiple shard moves in a sequential order by default. There are some cases where you may prefer to rebalance faster at the expense of using more resources such as network bandwidth. In those situations, customers are able to configure a rebalance operation to perform a number of shard moves in parallel.

The [citus.max\\_background\\_task\\_executors\\_per\\_node](#) configuration parameter allows tasks such as shard rebalancing to operate in parallel. You can increase it from its default value of 1 as desired to boost parallelism.

```
ALTER SYSTEM SET citus.max_background_task_executors_per_node = 2;  
SELECT pg_reload_conf();
```

```
SELECT citus_rebalance_start();
```

#### What are the typical use cases?

- Scaling out faster when adding new nodes to the cluster.
- Rebalancing the cluster faster to even out the utilization of nodes.

#### Corner Cases and Gotchas

The [citus.max\\_background\\_task\\_executors\\_per\\_node](#) configuration parameter limits the number of parallel task executors in general. Also, shards in the same colocation group will always move sequentially so parallelism may be limited by the number of colocation groups.

#### How it Works

citus shard rebalancing uses Postgres Pro logical replication to move data from the old shard (called the “publisher” in replication terms) to the new (the “subscriber”). Logical replication allows application reads and writes to continue uninterrupted while copying shard data. citus puts a brief write-lock on a shard only during the time it takes to update metadata to promote the subscriber shard as active.

As the Postgres Pro documentation [explains](#), the source needs a *replica identity* configured:

A published table must have a “replica identity” configured in order to be able to replicate `UPDATE` and `DELETE` operations, so that appropriate rows to update or delete can be identified on the subscriber side. By default, this is the primary key, if there is one. Another unique index (with certain additional requirements) can also be set to be the replica identity.

In other words, if your distributed table has a primary key defined then it is ready for shard rebalancing with no extra work. However, if it does not have a primary key or an explicitly defined replica identity, then attempting to rebalance it will cause an error. Here is how to fix it.

### First, does the table have a unique index?

If the table to be replicated already has a unique index, which includes the distribution column, then choose that index as a replica identity:

```
-- Supposing my_table has unique index my_table_idx
-- which includes distribution column

ALTER TABLE my_table REPLICA IDENTITY
    USING INDEX my_table_idx;
```

### Note

While `REPLICA IDENTITY USING INDEX` is fine, we recommend **against** adding `REPLICA IDENTITY FULL` to a table. This setting would result in each `UPDATE/DELETE` doing a full-table-scan on the subscriber side to find the tuple with those rows. In our testing we have found this to result in worse performance than even solution four below.

### Otherwise, can you add a primary key?

Add a primary key to the table. If the desired key happens to be the distribution column, then it's quite easy, just add the constraint. Otherwise, a primary key with a non-distribution column must be composite and contain the distribution column too.

#### J.5.8.1.3.3. Adding a Coordinator

The citus coordinator only stores metadata about the table shards and does not store any data. This means that all the computation is pushed down to the workers and the coordinator does only final aggregations on the result of the workers. Therefore, it is not very likely that the coordinator becomes a bottleneck for read performance. Also, it is easy to boost up the coordinator by shifting to a more powerful machine.

However, in some write-heavy use cases where the coordinator becomes a performance bottleneck, you can add another coordinator. As the metadata tables are small (typically a few MBs in size), it is possible to copy over the metadata onto another node and sync it regularly. Once this is done, users can send their queries to any coordinator and scale out performance.

#### J.5.8.1.4. Dealing With Node Failures

In this subsection, we discuss how you can deal with node failures without incurring any downtime on your citus cluster.

##### J.5.8.1.4.1. Worker Node Failures

citus uses Postgres Pro streaming replication, allowing it to tolerate worker-node failures. This option replicates entire worker nodes by continuously streaming their WAL records to a standby. You can configure streaming replication on-premise yourself by consulting the [Streaming Replication](#) section.

##### J.5.8.1.4.2. Coordinator Node Failures

The citus coordinator maintains metadata tables to track all of the cluster nodes and the locations of the database shards on those nodes. The metadata tables are small (typically a few MBs in size) and

do not change very often. This means that they can be replicated and quickly restored if the node ever experiences a failure. There are several options on how users can deal with coordinator failures.

- **Use Postgres Pro streaming replication.** You can use Postgres Pro streaming replication feature to create a hot standby of the coordinator. Then, if the primary coordinator node fails, the standby can be promoted to the primary automatically to serve queries to your cluster. For details on setting this up, please refer to the [Streaming Replication](#) section.
- **Use backup tools.** Since the metadata tables are small, users can use EBS volumes, or [Postgres Pro backup tools](#) to backup the metadata. Then, they can easily copy over that metadata to new nodes to resume operation.

#### J.5.8.1.5. Tenant Isolation

##### J.5.8.1.5.1. Row-Based Sharding

citux places table rows into worker shards based on the hashed value of the rows' distribution column. Multiple distribution column values often fall into the same shard. In the citux multi-tenant use case this means that tenants often share shards.

However, sharing shards can cause resource contention when tenants differ drastically in size. This is a common situation for systems with a large number of tenants — we have observed that the size of tenant data tend to follow a Zipfian distribution as the number of tenants increases. This means there are a few very large tenants, and many smaller ones. To improve resource allocation and make guarantees of tenant QoS it is worthwhile to move large tenants to dedicated nodes.

citux provides the tools to isolate a tenant on a specific node. This happens in two phases: firstly, isolating the tenant's data to a new dedicated shard, then moving the shard to the desired node. To understand the process, it helps to know precisely how rows of data are assigned to shards.

Every shard is marked in citux metadata with the range of hashed values it contains (more info in the reference for the [pg\\_dist\\_shard](#) table). The [isolate\\_tenant\\_to\\_new\\_shard](#) function moves a tenant into a dedicated shard in three steps:

1. Creates a new shard for `table_name`, which includes rows whose distribution column has value `tenant_id` and excludes all other rows.
2. Moves the relevant rows from their current shard to the new shard.
3. Splits the old shard into two with hash ranges that abut the excision above and below.

Furthermore, the function takes the `CASCADE` option, which isolates the tenant rows of not just `table_name` but of all tables [co-located](#) with it. Here is an example:

```
-- This query creates an isolated shard for the given tenant_id and
-- returns the new shard id.

-- General form:

SELECT isolate_tenant_to_new_shard('table_name', tenant_id);

-- Specific example:

SELECT isolate_tenant_to_new_shard('lineitem', 135);

-- If the given table has co-located tables, the query above errors out and
-- advises to use the CASCADE option

SELECT isolate_tenant_to_new_shard('lineitem', 135, 'CASCADE');
```

Output:

```
| isolate_tenant_to_new_shard |
```

|        |
|--------|
| 102240 |
|--------|

The new shard(s) are created on the same node as the shard(s) from which the tenant was removed. For true hardware isolation they can be moved to a separate node in the citus cluster. As mentioned, the `isolate_tenant_to_new_shard` function returns the newly created shard ID, and this ID can be used to move the shard:

#### J.5.8.1.5.2. Schema-Based Sharding

In schema-based sharding, the act of isolating a tenant is not required as by definition each tenant already resides in its own schema. The only thing that is needed is obtaining a shard identifier for a schema to perform a move.

First find the colocation ID of the schema you want to move.

```
SELECT * FROM citus_schemas;
```

| schema_name  | colocation_id | schema_size | schema_owner |
|--------------|---------------|-------------|--------------|
| user_service | 1             | 0 bytes     | user_service |
| time_service | 2             | 0 bytes     | time_service |
| ping_service | 3             | 0 bytes     | ping_service |
| a            | 4             | 128 kB      | citus        |
| b            | 5             | 32 kB       | citus        |
| with_data    | 11            | 6408 kB     | citus        |

(6 rows)

The next step is to query `citus_shards`, we will use co-location identifier 11 from the output above:

```
SELECT * FROM citus_shards where colocation_id = 11;
```

| table_name      | shardid  | shard_name             | citus_table_type | colocation_id |
|-----------------|----------|------------------------|------------------|---------------|
| nodename        | nodeport | shard_size             |                  |               |
| with_data.test  | 102180   | with_data.test_102180  | schema           | 11            |
| localhost       | 9702     | 647168                 |                  |               |
| with_data.test2 | 102183   | with_data.test2_102183 | schema           | 11            |
| localhost       | 9702     | 5914624                |                  |               |

(2 rows)

You can pick any `shardid` from the output as making the move will also propagate to all co-located tables, which in case of schema-based sharding means moving all tables within the schema.

#### J.5.8.1.5.3. Make the Move

Knowing the shard ID that denotes the tenant, you can execute the move:

```
-- Find the node currently holding the new shard
SELECT nodename, nodeport
FROM citus_shards
WHERE shardid = 102240;

-- List the available worker nodes that could hold the shard
SELECT * FROM master_get_active_worker_nodes();

-- Move the shard to your choice of worker
-- (it will also move any shards created with the CASCADE option)
SELECT citus_move_shard_placement(
    102240,
    'source_host', source_port,
```

```
'dest_host', dest_port);
```

Note that the `citus_move_shard_placement` function will also move any shards which are co-located with the specified one, to preserve their co-location.

#### J.5.8.1.6. Viewing Query Statistics

When administering a citus cluster it is useful to know what queries users are running, which nodes are involved, and which execution method citus is using for each query. The extension records query statistics in a metadata view called `citus_stat_statements`, named analogously to Postgres Pro `pg_stat_statements`. Whereas `pg_stat_statements` stores info about query duration and I/O, `citus_stat_statements` stores info about citus execution methods and shard partition keys (when applicable).

citus requires the `pg_stat_statements` extension to be installed in order to track query statistics. On a self-hosted Postgres Pro instance load the extension in `postgresql.conf` via `shared_preload_libraries`, then create the extension in SQL:

```
CREATE EXTENSION pg_stat_statements;
```

Let's see how this works. Assume we have a table called `foo` that is hash-distributed by its `id` column.

```
-- Create and populate distributed table
CREATE TABLE foo ( id int );
SELECT create_distributed_table('foo', 'id');

INSERT INTO foo SELECT generate_series(1,100);
```

We will run two more queries and `citus_stat_statements` will show how citus chooses to execute them.

```
-- Counting all rows executes on all nodes, and sums
-- the results on the coordinator
SELECT count(*) FROM foo;

-- Specifying a row by the distribution column routes
-- execution to an individual node
SELECT * FROM foo WHERE id = 42;
```

To find how these queries were executed, ask the stats table:

```
SELECT * FROM citus_stat_statements;
```

Results:

```
-[ RECORD 1 ]-+-----
queryid      | -6844578505338488014
userid       | 10
dbid         | 13340
query        | SELECT count(*) FROM foo;
executor     | adaptive
partition_key |
calls        | 1
-[ RECORD 2 ]-+-----
queryid      | 185453597994293667
userid       | 10
dbid         | 13340
query        | INSERT INTO foo SELECT generate_series($1,$2)
executor     | insert-select
partition_key |
calls        | 1
-[ RECORD 3 ]-+-----
queryid      | 1301170733886649828
userid       | 10
dbid         | 13340
```

```

query          | SELECT * FROM foo WHERE id = $1
executor       | adaptive
partition_key  | 42
calls          | 1

```

We can see that Citus uses the adaptive executor most commonly to run queries. This executor fragments the query into constituent queries to run on relevant nodes and combines the results on the coordinator node. In the case of the second query (filtering by the distribution column `id = $1`), Citus determined that it needed the data from just one node. Lastly, we can see that the `INSERT INTO foo SELECT...` statement ran with the `insert-select` executor that provides flexibility to run these kind of queries.

#### J.5.8.1.6.1. Tenant-Level Statistics

So far the information in this view does not give us anything we could not already learn by running the `EXPLAIN` command for a given query. However, in addition to getting information about individual queries, the `citus_stat_statements` view allows us to answer questions such as “what percentage of queries in the cluster are scoped to a single tenant?”

```

SELECT sum(calls),
       partition_key IS NOT NULL AS single_tenant
FROM citus_stat_statements
GROUP BY 2;

```

```

.
sum | single_tenant
-----+-----
  2 | f
  1 | t

```

In a multi-tenant database, for instance, we would expect the vast majority of queries to be single tenant. Seeing too many multi-tenant queries may indicate that queries do not have the proper filters to match a tenant, and are using unnecessary resources.

To investigate which tenants in particular are most active, you can use the `citus_stat_tenants` view.

#### J.5.8.1.6.2. Statistics Expiration

The `pg_stat_statements` view limits the number of statements it tracks and the duration of its records. Because the `citus_stat_statements` table tracks a strict subset of the queries in `pg_stat_statements`, a choice of equal limits for the two views would cause a mismatch in their data retention. Mismatched records can cause joins between the views to behave unpredictably.

There are three ways to help synchronize the views, and all three can be used together.

1. Have the maintenance daemon periodically sync the Citus and Postgres Pro statistics. The `citus.stat_statements_purge_interval` configuration parameter sets time in seconds for the sync. A value of 0 disables periodic syncs.
2. Adjust the number of entries in `citus_stat_statements`. The `citus.stat_statements_max` configuration parameter removes old entries when new ones cross the threshold. The default value is 50000, and the highest allowable value is 10000000. Note that each entry costs about 140 bytes in shared memory so set the value wisely.
3. Increase `pg_stat_statements.max`. Its default value is 5000 and could be increased to 10000, 20000 or even 50000 without much overhead. This is most beneficial when there is more local (i.e. coordinator) query workload.

### Note

Changing `pg_stat_statements.max` or `citus.stat_statements_max` requires restarting the Postgres Pro service. Changing `citus.stat_statements_purge_interval`, on the other hand, will come into effect with a call to the `pg_reload_conf` function.

### J.5.8.1.7. Resource Conservation

#### J.5.8.1.7.1. Limiting Long-Running Queries

Long running queries can hold locks, queue up WAL, or just consume a lot of system resources, so in a production environment it is good to prevent them from running too long. You can set the [statement\\_timeout](#) parameter on the coordinator and workers to cancel queries that run too long.

```
-- Limit queries to five minutes
ALTER DATABASE citus
  SET statement_timeout TO 300000;
SELECT run_command_on_workers($cmd$
  ALTER DATABASE citus
    SET statement_timeout TO 300000;
$cmd$);
```

The timeout is specified in milliseconds.

To customize the timeout per query, use `SET LOCAL` in a transaction:

```
BEGIN;
-- this limit applies to just the current transaction
SET LOCAL statement_timeout TO 300000;

-- ...
COMMIT;
```

### J.5.8.1.8. Security

#### J.5.8.1.8.1. Connection Management

#### Note

The traffic between the different nodes in the cluster is encrypted for new installations. This is done by using TLS with self-signed certificates. This means that this **does not protect against man-in-the-middle attacks**. This only protects against passive eavesdropping on the network.

Clusters originally created with citus do not have any network encryption enabled between nodes (even if upgraded later). To set up self-signed TLS on this type of installation follow the steps in the [Creating Certificates](#) section together with the citus specific settings described here, i.e. changing the [citus.node\\_conninfo](#) parameter to `sslmode=require`. This setup should be done on the coordinator and workers.

When citus nodes communicate with one another they consult a table with connection credentials. This gives the database administrator flexibility to adjust parameters for security and efficiency.

To set non-sensitive libpq connection parameters to be used for all node connections, update the `citus.node_conninfo` configuration parameter:

```
-- key=value pairs separated by spaces.
-- For example, ssl options:

ALTER SYSTEM SET citus.node_conninfo =
  'sslrootcert=/path/to/citus-ca.crt sslcrl=/path/to/citus-ca.crl sslmode=verify-full';
```

There is a whitelist of options that the [citus.node\\_conninfo](#) configuration parameter accepts. The default value is `sslmode=require`, which prevents unencrypted communication between nodes. If your cluster was originally created with citus, the value will be `sslmode=prefer`. After setting up self-signed certificates on all nodes it is recommended to change this setting to `sslmode=require`.

After changing this setting it is important to reload the Postgres Pro configuration. Even though the changed setting might be visible in all sessions, the setting is only consulted by citus when new connections are established. When a reload signal is received, citus marks all existing connections to be closed which causes a reconnect after running transactions have been completed.

```
SELECT pg_reload_conf();

-- Only superusers can access this table

-- Add a password for user jdoe
INSERT INTO pg_dist_authinfo
    (nodeid, rolename, authinfo)
VALUES
    (123, 'jdoe', 'password=abc123');
```

After this `INSERT`, any query needing to connect to node 123 as the user `jdoe` will use the supplied password. To learn more, see the section about the `pg_dist_authinfo` table.

```
-- Update user jdoe to use certificate authentication
UPDATE pg_dist_authinfo
SET authinfo = 'sslcert=/path/to/user.crt sslkey=/path/to/user.key'
WHERE nodeid = 123 AND rolename = 'jdoe';
```

This changes the user from using a password to use a certificate and keyfile while connecting to node 123 instead. Make sure the user certificate is signed by a certificate that is trusted by the worker you are connecting to and authentication settings on the worker allow for certificate based authentication. Full documentation on how to use client certificates can be found in the [Client Certificates](#) section.

Changing the `pg_dist_authinfo` table does not force any existing connection to reconnect.

#### J.5.8.1.8.2. Setup Certificate Authority Signed Certificates

This section assumes you have a trusted Certificate Authority that can issue server certificates to you for all nodes in your cluster. It is recommended to work with the security department in your organization to prevent key material from being handled incorrectly. This guide covers only citus specific configuration that needs to be applied, not best practices for PKI management.

For all nodes in the cluster you need to get a valid certificate signed by the *same Certificate Authority*. The following machine-specific files are assumed to be available on every machine:

- `/path/to/server.key` — Server Private Key
- `/path/to/server.crt` — Server Certificate or Certificate Chain for Server Key, signed by trusted Certificate Authority

Next to these machine-specific files you need these cluster or Certificate Authority wide files available:

- `/path/to/ca.crt` — Certificate of the Certificate Authority
- `/path/to/ca.crl` — Certificate Revocation List of the Certificate Authority

### Note

The Certificate Revocation List is likely to change over time. Work with your security department to set up a mechanism to update the revocation list on to all nodes in the cluster in a timely manner. A reload of every node in the cluster is required after the revocation list has been updated.

Once all files are in place on the nodes, the following settings need to be configured in the Postgres configuration file:

```
# The following settings allow the postgres server to enable ssl, and
# configure the server to present the certificate to clients when
# connecting over tls/ssl
```

```
ssl = on
ssl_key_file = '/path/to/server.key'
ssl_cert_file = '/path/to/server.crt'
```

```
# This will tell citus to verify the certificate of the server it is connecting to
citus.node_conninfo = 'sslmode=verify-full sslrootcert=/path/to/ca.crt sslcrl=/path/to/ca.crl'
```

After changing, reload the configuration to apply these changes. Also, adjusting [citus.local\\_hostname](#) may be required for proper functioning with `sslmode=verify-full`.

Depending on the policy of the Certificate Authority used you might need or want to change `sslmode=verify-full` in [citus.node\\_conninfo](#) to `sslmode=verify-ca`. For the difference between the two settings, consult the [SSL Mode Descriptions](#) section.

Lastly, to prevent any user from connecting via an un-encrypted connection, changes need to be made to `pg_hba.conf`. Many Postgres Pro installations will have entries allowing `host` connections which allow SSL/TLS connections as well as plain TCP connections. By replacing all `host` entries with `hostssl` entries, only encrypted connections will be allowed to authenticate to Postgres Pro. For full documentation on these settings take a look at the section about the `pg_hba.conf` file.

### Note

When a trusted Certificate Authority is not available, one can create their own via a self-signed root certificate. This is non-trivial and the developer or operator should seek guidance from their security team when doing so.

To verify the connections from the coordinator to the workers are encrypted you can run the following query. It will show the SSL/TLS version used to encrypt the connection that the coordinator uses to talk to the worker:

```
SELECT run_command_on_workers($$
  SELECT version FROM pg_stat_ssl WHERE pid = pg_backend_pid()
$$);
```

| run_command_on_workers     |
|----------------------------|
| (localhost,9701,t,TLSv1.2) |
| (localhost,9702,t,TLSv1.2) |

(2 rows)

#### J.5.8.1.8.3. Increasing Worker Security

For your convenience getting started, our [multi-node installation instructions](#) direct you to set up the `pg_hba.conf` on the workers with its [authentication method](#) set to `trust` for local network connections. However, you might desire more security.

To require that all connections supply a hashed password, update the Postgres Pro `pg_hba.conf` on every worker node with something like this:

```
# Require password access and a ssl/tls connection to nodes in the local
# network. The following ranges correspond to 24, 20, and 16-bit blocks
# in Private IPv4 address spaces.
hostssl      all             all             10.0.0.0/8          md5

# Require passwords and ssl/tls connections when the host connects to
# itself as well.
hostssl      all             all             127.0.0.1/32        md5
```

```
hostssl      all          all          :::1/128      md5
```

The coordinator node needs to know roles' passwords in order to communicate with the workers. In citus the authentication information has to be maintained in the `.pgpass` file. Edit the file in the Postgres Pro user home directory, with a line for each combination of worker address and role:

```
hostname:port:database:username:password
```

Sometimes workers need to connect to one another, such as during [repartition joins](#). Thus each worker node requires a copy of the `.pgpass` file as well.

#### J.5.8.1.8.4. Row-Level Security

Postgres Pro [row-level security](#) policies restrict, on a per-user basis, which rows can be returned by normal queries or inserted, updated, or deleted by data modification commands. This can be especially useful in a multi-tenant citus cluster because it allows individual tenants to have full SQL access to the database while hiding each tenant's information from other tenants.

We can implement the separation of tenant data by using a naming convention for database roles that ties into table row-level security policies. We will assign each tenant a database role in a numbered sequence: `tenant_1`, `tenant_2`, etc. Tenants will connect to citus using these separate roles. Row-level security policies can compare the role name to values in the `tenant_id` distribution column to decide whether to allow access.

Here is how to apply the approach on a simplified events table distributed by `tenant_id`. First create the roles `tenant_1` and `tenant_2`. Then run the following as an administrator:

```
CREATE TABLE events (
    tenant_id int,
    id int,
    type text
);

SELECT create_distributed_table('events','tenant_id');

INSERT INTO events VALUES (1,1,'foo'), (2,2,'bar');

-- Assumes that roles tenant_1 and tenant_2 exist
GRANT select, update, insert, delete
    ON events TO tenant_1, tenant_2;
```

As it stands, anyone with `SELECT` permissions for this table can see both rows. Users from either tenant can see and update the row of the other tenant. We can solve this with row-level table security policies.

Each policy consists of two clauses: `USING` and `WITH CHECK`. When a user tries to read or write rows, the database evaluates each row against these clauses. Existing table rows are checked against the expression specified in `USING`, while new rows that would be created via `INSERT` or `UPDATE` are checked against the expression specified in `WITH CHECK`.

```
-- First a policy for the system admin "citus" user
CREATE POLICY admin_all ON events
    TO citus          -- apply to this role
    USING (true)      -- read any existing row
    WITH CHECK (true); -- insert or update any row

-- Next a policy which allows role "tenant_<n>" to
-- access rows where tenant_id = <n>
CREATE POLICY user_mod ON events
    USING (current_user = 'tenant_' || tenant_id::text);
-- Lack of CHECK means same condition as USING
```

```
-- Enforce the policies
ALTER TABLE events ENABLE ROW LEVEL SECURITY;
```

Now roles `tenant_1` and `tenant_2` get different results for their queries:

Connected as `tenant_1`:

```
SELECT * FROM events;
```

| tenant_id | id | type |
|-----------|----|------|
| 1         | 1  | foo  |

Connected as `tenant_2`:

```
SELECT * FROM events;
```

| tenant_id | id | type |
|-----------|----|------|
| 2         | 2  | bar  |

```
INSERT INTO events VALUES (3,3,'surprise');
/*
ERROR:  new row violates row-level security policy for table "events_102055"
*/
```

#### J.5.8.1.9. Postgres Pro extensions

`citus` provides distributed functionality by extending Postgres Pro using the hook and extension APIs. This allows users to benefit from the features that come with the rich Postgres Pro ecosystem. These features include, but are not limited to, support for a wide range of [data types](#) (including semi-structured data types like `jsonb` and `hstore`), [operators and functions](#), full text search, and other extensions such as [PostGIS](#) and [HyperLogLog](#). Further, proper use of the extension APIs enable compatibility with standard Postgres Pro tools such as [pgAdmin](#) and [pg\\_upgrade](#).

As `citus` is an extension which can be installed on any Postgres Pro instance, you can directly use other extensions such as `hstore`, `hll`, or `PostGIS` with `citus`. However, there is one thing to keep in mind. While including other extensions in `shared_preload_libraries`, you should make sure that `citus` is the first extension.

There are several extensions, which may be useful when working with `citus`:

- [cstore\\_fdw](#) — columnar store for analytics. The columnar nature delivers performance by reading only relevant data from disk, and it may compress data 6x-10x to reduce space requirements for data archival.
- [pg\\_cron](#) — run periodic jobs directly from the database.
- [topn](#) — returns the top values in a database according to some criteria. Uses an approximation algorithm to provide fast results with modest compute and memory resources.
- [hll](#) — HyperLogLog data structure as a native data type. It is a fixed-size, set-like structure used for distinct value counting with tunable precision.

#### J.5.8.1.10. Creating a New Database

Each Postgres Pro server can hold [multiple databases](#). However, new databases do not inherit the extensions of any others; all desired extensions must be added afresh. To run `citus` on a new database, you will need to create the database on the coordinator and workers, create the `citus` extension within that database, and register the workers in the coordinator database.

Connect to each of the worker nodes and run:

```
-- On every worker node

CREATE DATABASE newbie;
\c newbie
CREATE EXTENSION citus;
```

Then, on the coordinator:

```
CREATE DATABASE newbie;
\c newbie
CREATE EXTENSION citus;

SELECT * from citus_add_node('node-name', 5432);
SELECT * from citus_add_node('node-name2', 5432);
-- ... for all of them
```

Now the new database will be operating as another citus cluster.

## J.5.8.2. Table Management

### J.5.8.2.1. Determining Table and Relation Size

The usual way to find table sizes in Postgres Pro, [pg\\_total\\_relation\\_size](#), drastically under-reports the size of distributed tables. All this function does on a citus cluster is reveal the size of tables on the coordinator node. In reality the data in distributed tables lives on the worker nodes (in shards), not on the coordinator. A true measure of distributed table size is obtained as a sum of shard sizes. citus provides helper functions to query this information.

| Function                                  | Returns                                                                                                                                                                                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">citus_relation_size</a>       | <ul style="list-style-type: none"> <li>Size of actual data in table (the “<a href="#">main fork</a>”)</li> <li>A relation can be the name of a table or an index</li> </ul>                                                                                 |
| <a href="#">citus_table_size</a>          | <ul style="list-style-type: none"> <li>Output of the <a href="#">citus_relation_size</a> plus: <ul style="list-style-type: none"> <li>size of the <a href="#">free space map</a></li> <li>size of the <a href="#">visibility map</a></li> </ul> </li> </ul> |
| <a href="#">citus_total_relation_size</a> | <ul style="list-style-type: none"> <li>Output of the <a href="#">citus_table_size</a> plus: <ul style="list-style-type: none"> <li>size of indices</li> </ul> </li> </ul>                                                                                   |

These functions are analogous to three of the standard Postgres Pro [object size functions](#), with the additional note that if they cannot connect to a node, they error out.

Here is an example of using one of the helper functions to list the sizes of all distributed tables:

```
SELECT logicalrelid AS name,
       pg_size_pretty(citus_table_size(logicalrelid)) AS size
FROM pg_dist_partition;
```

Output:

| name          | size  |
|---------------|-------|
| github_users  | 39 MB |
| github_events | 37 MB |

### J.5.8.2.2. Vacuuming Distributed Tables

In Postgres Pro (and other MVCC databases), an `UPDATE` or `DELETE` of a row does not immediately remove the old version of the row. The accumulation of outdated rows is called bloat and must be cleaned to

avoid decreased query performance and unbounded growth of disk space requirements. Postgres Pro runs a process called the auto-vacuum daemon that periodically vacuums (removes) outdated rows.

It is not just user queries which scale in a distributed database, vacuuming does too. In Postgres Pro big busy tables have great potential to bloat, both from lower sensitivity to Postgres Pro vacuum scale factor parameter, and generally because of the extent of their row churn. Splitting a table into distributed shards means both that individual shards are smaller tables and that auto-vacuum workers can parallelize over different parts of the table on different machines. Ordinarily auto-vacuum can only run one worker per table.

Due to the above, auto-vacuum operations on a citus cluster are probably good enough for most cases. However, for tables with particular workloads, or companies with certain “safe” hours to schedule a vacuum, it might make more sense to manually vacuum a table rather than leaving all the work to auto-vacuum.

To vacuum a table, simply run this on the coordinator node:

```
VACUUM my_distributed_table;
```

Using vacuum against a distributed table will send the `VACUUM` command to every one of that table's placements (one connection per placement). This is done in parallel. All [options](#) are supported (including the `table_and_columns` list) except for `VERBOSE`. The `VACUUM` command also runs on the coordinator, and does so before any workers nodes are notified. Note that unqualified vacuum commands (i.e. those without a table specified) do not propagate to worker nodes.

#### J.5.8.2.3. Analyzing Distributed Tables

Postgres Pro `ANALYZE` command collects statistics about the contents of tables in the database. Subsequently, the query planner uses these statistics to help determine the most efficient execution plans for queries.

The auto-vacuum daemon, discussed in the previous section, will automatically issue `ANALYZE` commands whenever the content of a table has changed sufficiently. The daemon schedules `ANALYZE` strictly as a function of the number of rows inserted or updated; it has no knowledge of whether that will lead to meaningful statistical changes. Administrators might prefer to manually schedule `ANALYZE` operations instead, to coincide with statistically meaningful table changes.

To analyze a table, run this on the coordinator node:

```
ANALYZE my_distributed_table;
```

citus propagates the `ANALYZE` command to all worker node placements.

#### J.5.8.2.4. Columnar Storage

citus provides append-only columnar table storage for analytic and data warehousing workloads. When columns (rather than rows) are stored contiguously on disk, data becomes more compressible, and queries can request a subset of columns more quickly.

##### J.5.8.2.4.1. Usage

To use columnar storage, specify `USING columnar` when creating a table:

```
CREATE TABLE contestant (  
    handle TEXT,  
    birthdate DATE,  
    rating INT,  
    percentile FLOAT,  
    country CHAR(3),  
    achievements TEXT[]  
) USING columnar;
```

You can also convert between row-based (heap) and columnar storage.

```
-- Convert to row-based (heap) storage
SELECT alter_table_set_access_method('contestant', 'heap');

-- Convert to columnar storage (indexes will be dropped)
SELECT alter_table_set_access_method('contestant', 'columnar');
```

citus converts rows to columnar storage in “stripes” during insertion. Each stripe holds one transaction's worth of data, or 150000 rows, whichever is less. (The stripe size and other parameters of a columnar table can be changed with the [alter\\_columnar\\_table\\_set](#) function.)

For example, the following statement puts all five rows into the same stripe, because all values are inserted in a single transaction:

```
-- Insert these values into a single columnar stripe

INSERT INTO contestant VALUES
  ('a', '1990-01-10', 2090, 97.1, 'XA', '{a}'),
  ('b', '1990-11-01', 2203, 98.1, 'XA', '{a,b}'),
  ('c', '1988-11-01', 2907, 99.4, 'XB', '{w,y}'),
  ('d', '1985-05-05', 2314, 98.3, 'XB', '{}'),
  ('e', '1995-05-05', 2236, 98.2, 'XC', '{a}');
```

It is best to make large stripes when possible, because citus compresses columnar data separately per stripe. We can see facts about our columnar table like compression rate, number of stripes, and average rows per stripe by using `VACUUM VERBOSE`:

```
VACUUM VERBOSE contestant;

INFO:  statistics for "contestant":
storage id: 100000000000
total file size: 24576, total data size: 248
compression rate: 1.31x
total row count: 5, stripe count: 1, average rows per stripe: 5
chunk count: 6, containing data for dropped columns: 0, zstd compressed: 6
```

The output shows that citus used the `zstd` compression algorithm to obtain 1.31x data compression. The compression rate compares the size of inserted data as it was staged in memory against the size of that data compressed in its eventual stripe.

Because of how it is measured, the compression rate may or may not match the size difference between row and columnar storage for a table. The only way to truly find that difference is to construct a row and columnar table that contain the same data and compare.

#### J.5.8.2.4.2. Measuring Compression

Let's create a new example with more data to benchmark the compression savings.

```
-- First a wide table using row storage
CREATE TABLE perf_row(
  c00 int8, c01 int8, c02 int8, c03 int8, c04 int8, c05 int8, c06 int8, c07 int8, c08
int8, c09 int8,
  c10 int8, c11 int8, c12 int8, c13 int8, c14 int8, c15 int8, c16 int8, c17 int8, c18
int8, c19 int8,
  c20 int8, c21 int8, c22 int8, c23 int8, c24 int8, c25 int8, c26 int8, c27 int8, c28
int8, c29 int8,
  c30 int8, c31 int8, c32 int8, c33 int8, c34 int8, c35 int8, c36 int8, c37 int8, c38
int8, c39 int8,
  c40 int8, c41 int8, c42 int8, c43 int8, c44 int8, c45 int8, c46 int8, c47 int8, c48
int8, c49 int8,
  c50 int8, c51 int8, c52 int8, c53 int8, c54 int8, c55 int8, c56 int8, c57 int8, c58
int8, c59 int8,
```

```

    c60 int8, c61 int8, c62 int8, c63 int8, c64 int8, c65 int8, c66 int8, c67 int8, c68
int8, c69 int8,
    c70 int8, c71 int8, c72 int8, c73 int8, c74 int8, c75 int8, c76 int8, c77 int8, c78
int8, c79 int8,
    c80 int8, c81 int8, c82 int8, c83 int8, c84 int8, c85 int8, c86 int8, c87 int8, c88
int8, c89 int8,
    c90 int8, c91 int8, c92 int8, c93 int8, c94 int8, c95 int8, c96 int8, c97 int8, c98
int8, c99 int8
);

```

```

-- Next a table with identical columns using columnar storage
CREATE TABLE perf_columnar(LIKE perf_row) USING COLUMNAR;

```

**Fill both tables with the same large dataset:**

```

INSERT INTO perf_row
SELECT
    g % 00500, g % 01000, g % 01500, g % 02000, g % 02500, g % 03000, g % 03500, g %
04000, g % 04500, g % 05000,
    g % 05500, g % 06000, g % 06500, g % 07000, g % 07500, g % 08000, g % 08500, g %
09000, g % 09500, g % 10000,
    g % 10500, g % 11000, g % 11500, g % 12000, g % 12500, g % 13000, g % 13500, g %
14000, g % 14500, g % 15000,
    g % 15500, g % 16000, g % 16500, g % 17000, g % 17500, g % 18000, g % 18500, g %
19000, g % 19500, g % 20000,
    g % 20500, g % 21000, g % 21500, g % 22000, g % 22500, g % 23000, g % 23500, g %
24000, g % 24500, g % 25000,
    g % 25500, g % 26000, g % 26500, g % 27000, g % 27500, g % 28000, g % 28500, g %
29000, g % 29500, g % 30000,
    g % 30500, g % 31000, g % 31500, g % 32000, g % 32500, g % 33000, g % 33500, g %
34000, g % 34500, g % 35000,
    g % 35500, g % 36000, g % 36500, g % 37000, g % 37500, g % 38000, g % 38500, g %
39000, g % 39500, g % 40000,
    g % 40500, g % 41000, g % 41500, g % 42000, g % 42500, g % 43000, g % 43500, g %
44000, g % 44500, g % 45000,
    g % 45500, g % 46000, g % 46500, g % 47000, g % 47500, g % 48000, g % 48500, g %

```
VACUUM (FREEZE, ANALYZE) perf_row;
VACUUM (FREEZE, ANALYZE) perf_columnar;
```

For this data, you can see a compression ratio of better than 8X in the columnar table.

```
SELECT pg_total_relation_size('perf_row')::numeric/
       pg_total_relation_size('perf_columnar') AS compression_ratio;

.
compression_ratio
-----
8.0196135873627944
(1 row)
```

#### J.5.8.2.4.3. Example

Columnar storage works well with table partitioning. For example, see the [Archiving with Columnar Storage](#) section.

#### J.5.8.2.4.4. Gotchas

- Columnar storage compresses per stripe. Stripes are created per transaction, so inserting one row per transaction will put single rows into their own stripes. Compression and performance of single row stripes will be worse than a row table. Always insert in bulk to a columnar table.
- If you mess up and columnarize a bunch of tiny stripes, there is no way to repair the table. The only fix is to create a new columnar table and copy data from the original in one transaction:

```
BEGIN;
CREATE TABLE foo_compacted (LIKE foo) USING columnar;
INSERT INTO foo_compacted SELECT * FROM foo;
DROP TABLE foo;
ALTER TABLE foo_compacted RENAME TO foo;
COMMIT;
```

- Fundamentally non-compressible data can be a problem, although it can still be useful to use columnar so that less is loaded into memory when selecting specific columns.
- On a partitioned table with a mix of row and column partitions, updates must be carefully targeted or filtered to hit only the row partitions.
  - If the operation is targeted at a specific row partition (e.g. `UPDATE p2 SET i = i + 1`), it will succeed; if targeted at a specified columnar partition (e.g. `UPDATE p1 SET i = i + 1`), it will fail.
  - If the operation is targeted at the partitioned table and has a `WHERE` clause that excludes all columnar partitions (e.g. `UPDATE parent SET i = i + 1 WHERE timestamp = '2020-03-15'`), it will succeed.
  - If the operation is targeted at the partitioned table, but does not exclude all columnar partitions, it will fail; even if the actual data to be updated only affects row tables (e.g. `UPDATE parent SET i = i + 1 WHERE n = 300`).

#### J.5.8.2.4.5. Limitations

Future versions of citus will incrementally lift the current limitations:

- Append-only (no `UPDATE/DELETE` support)
- No space reclamation (e.g. rolled-back transactions may still consume disk space)
- Support for hash and btree indices only
- No index scans, or bitmap index scans

- No TID scan
- No sample scans
- No TOAST support (large values supported inline)
- No support for `ON CONFLICT` statements (except `DO NOTHING` actions with no target specified)
- No support for tuple locks (`SELECT ... FOR SHARE`, `SELECT ... FOR UPDATE`)
- No support for serializable isolation level
- Support for Postgres Pro server versions 12+ only
- No support for foreign keys, unique constraints, or exclusion constraints
- No support for logical decoding
- No support for intra-node parallel scans
- No support for `AFTER ... FOR EACH ROW` triggers
- No `UNLOGGED` columnar tables
- No `TEMPORARY` columnar tables

## J.5.9. Troubleshoot

### J.5.9.1. Query Performance Tuning

In this section, we describe how you can tune your citus cluster to get maximum performance. We begin by explaining how choosing the right distribution column affects performance. We then describe how you can first tune your database for high performance on one Postgres Pro server and then scale it out across all the CPUs in the cluster. In this section, we also discuss several performance related configuration parameters wherever relevant.

#### J.5.9.1.1. Table Distribution and Shards

The first step while creating a distributed table is choosing the right distribution column. This helps citus push down several operations directly to the worker shards and prune away unrelated shards, which lead to significant query speedups.

Typically, you should pick that column as the distribution column which is the most commonly used join key or on which most queries have filters. For filters, citus uses the distribution column ranges to prune away unrelated shards, ensuring that the query hits only those shards which overlap with the `WHERE` clause ranges. For joins, if the join key is the same as the distribution column, then citus executes the join only between those shards, which have matching / overlapping distribution column ranges. All these shard joins can be executed in parallel on the workers and hence are more efficient.

In addition, citus can push down several operations directly to the worker shards if they are based on the distribution column. This greatly reduces both the amount of computation on each node and the network bandwidth involved in transferring data across nodes.

Once you choose the right distribution column, you can then proceed to the next step, which is tuning worker node performance.

#### J.5.9.1.2. Postgres Pro Tuning

The citus coordinator partitions an incoming query into fragment queries and sends them to the workers for parallel processing. The workers are just extended Postgres Pro servers and they apply Postgres Pro standard planning and execution logic for these queries. So, the first step in tuning citus is tuning the Postgres Pro configuration parameters on the workers for high performance.

Tuning the parameters is a matter of experimentation and often takes several attempts to achieve acceptable performance. Thus it is best to load only a small portion of your data when tuning to make each iteration go faster.

To begin the tuning process create a citus cluster and load data in it. From the coordinator node, run the `EXPLAIN` command on representative queries to inspect performance. citus extends the `EXPLAIN` command to provide information about distributed query execution. The `EXPLAIN` output shows how each worker processes the query and also a little about how the coordinator node combines their results.

Here is an example of explaining the plan for a particular example query. We use the `VERBOSE` flag to see the actual queries, which were sent to the worker nodes.

```
EXPLAIN VERBOSE
SELECT date_trunc('minute', created_at) AS minute,
       sum((payload->>'distinct_size')::int) AS num_commits
FROM   github_events
WHERE  event_type = 'PushEvent'
GROUP BY minute
ORDER BY minute;

Sort  (cost=0.00..0.00 rows=0 width=0)
  Sort Key: remote_scan.minute
-> HashAggregate  (cost=0.00..0.00 rows=0 width=0)
   Group Key: remote_scan.minute
-> Custom Scan (Citrus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
   Task Count: 32
   Tasks Shown: One of 32
-> Task
    Query: SELECT date_trunc('minute'::text, created_at) AS minute, sum(((payload
OPERATOR(pg_catalog.->>) 'distinct_size'::text))::integer) AS num_commits FROM
github_events_102042 github_events WHERE (event_type OPERATOR(pg_catalog.=)
'PushEvent'::text) GROUP BY (date_trunc('minute'::text, created_at))
   Node: host=localhost port=5433 dbname=postgres
-> HashAggregate  (cost=93.42..98.36 rows=395 width=16)
   Group Key: date_trunc('minute'::text, created_at)
-> Seq Scan on github_events_102042 github_events  (cost=0.00..88.20
rows=418 width=503)
   Filter: (event_type = 'PushEvent'::text)

(13 rows)
```

This tells you several things. To begin with there are 32 shards, and the planner chose the citrus adaptive executor to execute this query:

```
-> Custom Scan (Citrus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
   Task Count: 32
```

Next it picks one of the workers and shows you more about how the query behaves there. It indicates the host, port, database, and the query that was sent to the worker so you can connect to the worker directly and try the query if desired:

```
Tasks Shown: One of 32
-> Task
   Query: SELECT date_trunc('minute'::text, created_at) AS minute, sum(((payload
OPERATOR(pg_catalog.->>) 'distinct_size'::text))::integer) AS num_commits FROM
github_events_102042 github_events WHERE (event_type OPERATOR(pg_catalog.=)
'PushEvent'::text) GROUP BY (date_trunc('minute'::text, created_at))
   Node: host=localhost port=5433 dbname=postgres
```

Distributed `EXPLAIN` next shows the results of running a normal Postgres Pro `EXPLAIN` on that worker for the fragment query:

```
-> HashAggregate  (cost=93.42..98.36 rows=395 width=16)
   Group Key: date_trunc('minute'::text, created_at)
-> Seq Scan on github_events_102042 github_events  (cost=0.00..88.20 rows=418
width=503)
   Filter: (event_type = 'PushEvent'::text)
```

You can now connect to the worker at `localhost`, port 5433 and tune query performance for the shard `github_events_102042` using standard Postgres Pro techniques. As you make changes run `EXPLAIN` again from the coordinator or right on the worker.

The first set of such optimizations relates to configuration settings. Postgres Pro by default comes with conservative resource settings; and among these settings [shared\\_buffers](#) and [work\\_mem](#) are probably the most important ones in optimizing read performance. We discuss these parameters in brief below. Apart from them, several other configuration settings impact query performance. These settings are covered in more detail in the [Server Configuration](#) chapter.

The `shared_buffers` configuration parameter defines the amount of memory allocated to the database for caching data and defaults to 128MB. If you have a worker node with 1GB or more RAM, a reasonable starting value for `shared_buffers` is 1/4 of the memory in your system. There are some workloads where even larger settings for `shared_buffers` are effective, but given the way Postgres Pro also relies on the operating system cache, it is unlikely you will find using more than 25% of RAM to work better than a smaller amount.

If you do a lot of complex sorts, then increasing `work_mem` allows Postgres Pro to do larger in-memory sorts, which will be faster than disk-based equivalents. If you see lot of disk activity on your worker node inspite of having a decent amount of memory, then increasing `work_mem` to a higher value can be useful. This will help Postgres Pro in choosing more efficient query plans and allow for greater amount of operations to occur in memory.

Other than the above configuration settings, the Postgres Pro query planner relies on statistical information about the contents of tables to generate good plans. These statistics are gathered when `ANALYZE` is run, which is enabled by default. You can learn more about the Postgres Pro planner and the `ANALYZE` command in greater detail in the relevant [section](#).

Lastly, you can create indexes on your tables to enhance database performance. Indexes allow the database to find and retrieve specific rows much faster than it could do without an index. To choose which indexes give the best performance, you can run the query with the [EXPLAIN](#) command to view query plans and optimize the slower parts of the query. After an index is created, the system has to keep it synchronized with the table which adds overhead to data manipulation operations. Therefore, indexes that are seldom or never used in queries should be removed.

For write performance, you can use general Postgres Pro configuration tuning to increase `INSERT` rates. We commonly recommend increasing [checkpoint\\_timeout](#) and [max\\_wal\\_size](#) settings. Also, depending on the reliability requirements of your application, you can choose to change [fsync](#) or [synchronous\\_commit](#) values.

Once you have tuned a worker to your satisfaction you will have to manually apply those changes to the other workers as well. To verify that they are all behaving properly, set this configuration variable on the coordinator:

```
SET citus.explain_all_tasks = 1;
```

This will cause `EXPLAIN` to show the query plan for all tasks, not just one.

```
EXPLAIN
SELECT date_trunc('minute', created_at) AS minute,
       sum((payload->>'distinct_size')::int) AS num_commits
FROM   github_events
WHERE  event_type = 'PushEvent'
GROUP BY minute
ORDER BY minute;

Sort  (cost=0.00..0.00 rows=0 width=0)
  Sort Key: remote_scan.minute
-> HashAggregate  (cost=0.00..0.00 rows=0 width=0)
   Group Key: remote_scan.minute
-> Custom Scan (Citus Adaptive)  (cost=0.00..0.00 rows=0 width=0)
   Task Count: 32
   Tasks Shown: All
-> Task
```

```

Node: host=localhost port=5433 dbname=postgres
-> HashAggregate (cost=93.42..98.36 rows=395 width=16)
  Group Key: date_trunc('minute'::text, created_at)
  -> Seq Scan on github_events_102042 github_events (cost=0.00..88.20
rows=418 width=503)
    Filter: (event_type = 'PushEvent'::text)
-> Task
Node: host=localhost port=5434 dbname=postgres
-> HashAggregate (cost=103.21..108.57 rows=429 width=16)
  Group Key: date_trunc('minute'::text, created_at)
  -> Seq Scan on github_events_102043 github_events (cost=0.00..97.47
rows=459 width=492)
    Filter: (event_type = 'PushEvent'::text)
--
-- ... repeats for all 32 tasks
--   alternating between workers one and two
--   (running in this case locally on ports 5433, 5434)
--

```

(199 rows)

Differences in worker execution can be caused by tuning configuration differences, uneven data distribution across shards, or hardware differences between the machines. To get more information about the time it takes the query to run on each shard you can use `EXPLAIN ANALYZE`.

### Note

Note that when [citius.explain\\_all\\_tasks](#) is enabled, `EXPLAIN` plans are retrieved sequentially, which may take a long time for `EXPLAIN ANALYZE`.

`citius`, by default, sorts tasks by execution time in descending order. If [citius.explain\\_all\\_tasks](#) is disabled, then `citius` shows the single longest-running task. Please note that this functionality can be used only with `EXPLAIN ANALYZE`, since regular `EXPLAIN` does not execute the queries, and therefore does not know any execution times. To change the sort order, you can use the [citius.explain\\_analyze\\_sort\\_method](#) configuration parameter.

#### J.5.9.1.3. Scaling Out Performance

As mentioned, once you have achieved the desired performance for a single shard you can set similar configuration parameters on all your workers. As `citius` runs all the fragment queries in parallel across the worker nodes, users can scale out the performance of their queries to be the cumulative of the computing power of all of the CPU cores in the cluster assuming that the data fits in memory.

Users should try to fit as much of their working set in memory as possible to get best performance with `citius`. If fitting the entire working set in memory is not feasible, we recommend using SSDs over HDDs as a best practice. This is because HDDs are able to show decent performance when you have sequential reads over contiguous blocks of data, but have significantly lower random read / write performance. In cases where you have a high number of concurrent queries doing random reads and writes, using SSDs can improve query performance by several times as compared to HDDs. Also, if your queries are highly compute-intensive, it might be beneficial to choose machines with more powerful CPUs.

To measure the disk space usage of your database objects, you can log into the worker nodes and use [Postgres Pro administration functions](#) for individual shards. The `pg_total_relation_size` function can be used to get the total disk space used by a table. You can also use other functions mentioned in the Postgres Pro documentation to get more specific size information. On the basis of these statistics for a shard and the shard count, users can compute the hardware requirements for their cluster.

Another factor that affects performance is the number of shards per worker node. `citius` partitions an incoming query into its fragment queries which run on individual worker shards. Hence, the degree of

parallelism for each query is governed by the number of shards the query hits. To ensure maximum parallelism, you should create enough shards on each node such that there is at least one shard per CPU core. Another consideration to keep in mind is that Citus will prune away unrelated shards if the query has filters on the distribution column. So, creating more shards than the number of cores might also be beneficial so that you can achieve greater parallelism even after shard pruning.

#### J.5.9.1.4. Distributed Query Performance Tuning

Once you have distributed your data across the cluster, with each worker optimized for best performance, you should be able to see high performance gains on your queries. After this, the final step is to tune a few distributed performance tuning parameters.

Before we discuss the specific configuration parameters, we recommend that you measure query times on your distributed cluster and compare them with the single shard performance. This can be done by enabling, timing, and running the query on the coordinator node and running one of the fragment queries on the worker nodes. This helps in determining the amount of time spent on the worker nodes and the amount of time spent in fetching the data to the coordinator node. Then, you can figure out what the bottleneck is and optimize the database accordingly.

In this section, we discuss the parameters that help optimize the distributed query planner and executor. There are several relevant parameters and we discuss them in two sections about [general performance tuning](#) and [advanced performance tuning](#). The first section is sufficient for most use cases and covers all the common configs. The second covers parameters that may provide performance gains in specific use cases.

##### J.5.9.1.4.1. General Performance Tuning

For higher `INSERT` performance, the factor that impacts insert rates the most is the level of concurrency. You should try to run several concurrent `INSERT` statements in parallel. This way you can achieve very high insert rates if you have a powerful coordinator node and are able to use all the CPU cores on that node together.

##### Subquery/CTE Network Overhead

In the best case Citus can execute queries containing subqueries and CTEs in a single step. This is usually because both the main query and subquery filter by distribution column of tables in the same way and can be pushed down to worker nodes together. However, Citus is sometimes forced to execute subqueries *before* executing the main query, copying the intermediate subquery results to other worker nodes for use by the main query. This technique is called [subquery/CTE push-pull execution](#).

It is important to be aware when subqueries are executed in a separate step and avoid sending too much data between worker nodes. The network overhead will hurt performance. The `EXPLAIN` command allows you to discover how queries will be executed, including whether multiple steps are required. For a detailed example, see the [Subquery/CTE Push-Pull Execution](#) section.

Also you can defensively set a safeguard against large intermediate results. Adjust the [citus.max\\_intermediate\\_result\\_size](#) limit in a new connection to the coordinator node. By default the max intermediate result size is 1 GB, which is large enough to allow some inefficient queries. Try turning it down and running your queries:

```
-- Set a restrictive limit for intermediate results
SET citus.max_intermediate_result_size = '512kB';

-- Attempt to run queries
-- SELECT ...
```

If the query has subqueries or CTEs that exceed this limit, the query will be canceled and you will see an error message:

```
ERROR:  the intermediate result size exceeds citus.max_intermediate_result_size
        (currently 512 kB)
```

DETAIL: Citus restricts the size of intermediate results of complex subqueries and CTEs to avoid accidentally pulling large result sets into once place.  
HINT: To run the current query, set `citus.max_intermediate_result_size` to a higher value or `-1` to disable.

The size of intermediate results and their destination is available in `EXPLAIN ANALYZE` output:

```
EXPLAIN ANALYZE
WITH deleted_rows AS (
  DELETE FROM page_views WHERE tenant_id IN (3, 4) RETURNING *
), viewed_last_week AS (
  SELECT * FROM deleted_rows WHERE view_time > current_timestamp - interval '7 days'
)
SELECT count(*) FROM viewed_last_week;

Custom Scan (Citus Adaptive) (cost=0.00..0.00 rows=0 width=0) (actual

('{3,4}'::integer[]))
                Planning Time: 0.050 ms
                Execution Time: 363.426 ms
    Planning Time: 0.000 ms
    Execution Time: 364.241 ms
Task Count: 1
Tuple data received from nodes: 6 bytes
Tasks Shown: All
-> Task
    Tuple data received from node: 6 bytes
    Node: host=localhost port=5432 dbname=postgres
-> Aggregate (cost=33741.78..33741.79 rows=1 width=8) (actual
time=565.008..565.008 rows=1 loops=1)
    -> Function Scan on read_intermediate_result intermediate_result
(cost=0.00..29941.56 rows=1520087 width=0) (actual time=326.645..539.158 rows=651466
loops=1)
        Filter: (view_time > (CURRENT_TIMESTAMP - '7 days'::interval))
        Planning Time: 0.047 ms
        Execution Time: 569.026 ms
Planning Time: 1.522 ms
```

```
Execution Time: 7549.308 ms
```

In the above `EXPLAIN ANALYZE` output, you can see the following information about the intermediate results:

```
Intermediate Data Size: 26 MB
Result destination: Write locally
```

It tells us how large the intermediate results were and where the intermediate results were written to. In this case, they were written to the node coordinating the query execution, as specified by `Write locally`. For some other queries it can also be of the following format:

```
Intermediate Data Size: 26 MB
Result destination: Send to 2 nodes
```

Which means the intermediate result was pushed to 2 worker nodes and it involved more network traffic.

When using CTEs, or joins between CTEs and distributed tables, you can avoid push-pull execution by following these rules:

- Tables should be co-located.
- The CTE queries should not require any merge steps (e.g., `LIMIT` or `GROUP BY` on a non-distribution key).
- Tables and CTEs should be joined on distribution keys.

Also Postgres Pro allows citus to take advantage of *CTE inlining* to push CTEs down to workers in more circumstances. The inlining behavior can be controlled with the `MATERIALIZED` keyword. To learn more, see the [WITH Queries \(Common Table Expressions\)](#) section.

#### J.5.9.1.4.2. Advanced Performance Tuning

In this section, we discuss advanced performance tuning parameters. These parameters are applicable to specific use cases and may not be required for all deployments.

##### Connection Management

When executing multi-shard queries, citus must balance the gains from parallelism with the overhead from database connections. The [Query Execution](#) section explains the steps of turning queries into worker tasks and obtaining database connections to the workers.

- Set the [citus.max\\_adaptive\\_executor\\_pool\\_size](#) configuration parameter to a low value like 1 or 2 for transactional workloads with short queries (e.g. < 20ms of latency). For analytical workloads where parallelism is critical, leave this setting at its default value of 16.
- Set the [citus.executor\\_slow\\_start\\_interval](#) configuration parameter to a high value like 100 ms for transactional workloads comprised of short queries that are bound on network latency rather than parallelism. For analytical workloads, leave this setting at its default value of 10 ms.
- The default value of 1 for the [citus.max\\_cached\\_conns\\_per\\_worker](#) configuration parameter is reasonable. A larger value such as 2 might be helpful for clusters that use a small number of concurrent sessions, but it is not wise to go much further (e.g. 16 would be too high). If set too high, sessions will hold idle connections and use worker resources unnecessarily.
- Set the [citus.max\\_shared\\_pool\\_size](#) configuration parameter to match the [max\\_connections](#) setting of your *worker* nodes. This setting is mainly a fail-safe.

##### Task Assignment Policy

The citus query planner assigns tasks to the worker nodes based on shard locations. The algorithm used while making these assignments can be chosen by setting the [citus.task\\_assignment\\_policy](#) configuration parameter. Users can alter this configuration parameter to choose the policy, which works best for their use case.

The `greedy` policy aims to distribute tasks evenly across the workers. This policy is the default and works well in most of the cases. The `round-robin` policy assigns tasks to workers in a round-robin fashion alternating between different replicas. This enables much better cluster utilization when the shard count

for a table is low compared to the number of workers. The third policy is the `first-replica` policy that assigns tasks on the basis of the insertion order of placements (replicas) for the shards. With this policy, users can be sure of which shards will be accessed on each machine. This helps in providing stronger memory residency guarantees by allowing you to keep your working set in memory and use it for querying.

#### Binary protocol

In some cases, a large part of query time is spent in sending query results from workers to the coordinator. This mostly happens when queries request many rows (such as `SELECT * FROM table`), or when result columns use big types (like `hll` or `tdigest` from the `hll` and `tdigest` extensions).

In those cases it can be beneficial to set `citus.enable_binary_protocol` to `true`, which will change the encoding of the results to binary, rather than using text encoding. Binary encoding significantly reduces bandwidth for types that have a compact binary representation, such as `hll`, `tdigest`, `timestamp` and `double precision`. The default value for this configuration parameter is already `true`. So explicitly enabling it has no effect.

#### J.5.9.1.5. Scaling Out Data Ingestion

`citus` lets you scale out data ingestion to very high rates, but there are several trade-offs to consider in terms of application integration, throughput, and latency. In this section, we discuss different approaches to data ingestion, and provide guidelines for expected throughput and latency numbers.

##### J.5.9.1.5.1. Real-Time Insert and Updates

On the `citus` coordinator, you can perform `INSERT`, `INSERT .. ON CONFLICT`, `UPDATE`, and `DELETE` commands directly on distributed tables. When you issue one of these commands, the changes are immediately visible to the user.

When you run the `INSERT` (or another ingest command), `citus` first finds the right shard placements based on the value in the distribution column. `citus` then connects to the worker nodes storing the shard placements, and performs an `INSERT` on each of them. From the perspective of the user, the `INSERT` takes several milliseconds to process because of the network latency to worker nodes. The `citus` coordinator node, however, can process concurrent `INSERTS` to reach high throughputs.

##### J.5.9.1.5.2. Staging Data Temporarily

When loading data for temporary staging, consider using an `unlogged table`. These are tables which are not backed by the Postgres Pro write-ahead log. This makes them faster for inserting rows but not suitable for long term data storage. You can use an unlogged table as a place to load incoming data, prior to manipulating the data and moving it to permanent tables.

```
-- Example unlogged table
CREATE UNLOGGED TABLE unlogged_table (
    key text,
    value text
);

-- Its shards will be unlogged as well when
-- the table is distributed
SELECT create_distributed_table('unlogged_table', 'key');

-- Ready to load data
```

##### J.5.9.1.5.3. Bulk Copy (250K - 2M/s)

Distributed tables support the `COPY` from the `citus` coordinator for bulk ingestion, which can achieve much higher ingestion rates than `INSERT` statements.

`COPY` can be used to load data directly from an application using `COPY .. FROM STDIN`, from a file on the server, or program executed on the server.

```
COPY pgbench_history FROM STDIN WITH (FORMAT CSV);
```

In `psql`, the `\copy` command can be used to load data from the local machine. The `\COPY` command actually sends a `COPY .. FROM STDIN` command to the server before sending the local data, as would an application that loads data directly.

```
psql -c "\COPY pgbench_history FROM 'pgbench_history-2016-03-04.csv' (FORMAT CSV)"
```

A powerful feature of `COPY` for distributed tables is that it asynchronously copies data to the workers over many parallel connections, one for each shard placement. This means that data can be ingested using multiple workers and multiple cores in parallel. Especially when there are expensive indexes such as a GIN, this can lead to major performance boosts over ingesting into a regular Postgres Pro table.

From a throughput standpoint, you can expect data ingest ratios of 250K - 2M rows per second when using `COPY`.

### Note

Make sure your benchmarking setup is well configured so you can observe optimal `COPY` performance. Follow these tips:

- We recommend a large batch size (~ 50000-100000). You can benchmark with multiple files (1, 10, 1000, 10000, etc), each of that batch size.
- Use parallel ingestion. Increase the number of threads/ingestors to 2, 4, 8, 16 and run benchmarks.
- Use a compute-optimized coordinator. For the workers choose memory-optimized boxes with a decent number of vCPUs.
- Go with a relatively small shard count, 32 should suffice, but you could benchmark with 64, too.
- Ingest data for a suitable amount of time (say 2, 4, 8, 24 hrs). Longer tests are more representative of a production setup.

## J.5.9.2. Useful Diagnostic Queries

### J.5.9.2.1. Finding Which Shard Contains Data For a Specific Tenant

The rows of a distributed table are grouped into shards, and each shard is placed on a worker node in the citus cluster. In the multi-tenant citus use case we can determine which worker node contains the rows for a specific tenant by putting together two pieces of information: the `shard_id` associated with the `tenant_id`, and the shard placements on workers. The two can be retrieved together in a single query. Suppose our multi-tenant application's tenants are stores, and we want to find which worker node holds the data for `gap.com` (`id=4`, suppose).

To find the worker node holding the data for store `id=4`, ask for the placement of rows whose distribution column has value 4:

```
SELECT shardid, shardstate, shardlength, nodename, nodeport, placementid
FROM pg_dist_placement AS placement,
     pg_dist_node AS node
WHERE placement.groupid = node.groupid
     AND node.noderole = 'primary'
     AND shardid = (
         SELECT get_shard_id_for_distribution_column('stores', 4)
     );
```

The output contains the host and port of the worker database.

| shardid | shardstate | shardlength | nodename | nodeport | placementid |
|---------|------------|-------------|----------|----------|-------------|
|         |            |             |          |          |             |

|        |   |   |           |      |   |
|--------|---|---|-----------|------|---|
| 102009 | 1 | 0 | localhost | 5433 | 2 |
|--------|---|---|-----------|------|---|

### J.5.9.2.2. Finding Which Node Hosts a Distributed Schema

Distributed schemas are automatically associated with individual co-location groups such that the tables created in those schemas are converted to co-located distributed tables without a shard key. You can find where a distributed schema resides by joining the [citus\\_shards](#) view with the [citus\\_schemas](#) view:

```
SELECT schema_name, nodename, nodeport
FROM citus_shards
JOIN citus_schemas cs
ON cs.colocation_id = citus_shards.colocation_id
GROUP BY 1,2,3;
```

| schema_name | nodename  | nodeport |
|-------------|-----------|----------|
| a           | localhost | 9701     |
| b           | localhost | 9702     |
| with_data   | localhost | 9702     |

You can also query `citus_shards` directly filtering down to schema table type to have a detailed listing for all tables.

```
SELECT * FROM citus_shards WHERE citus_table_type = 'schema';
```

| table_name     | shardid | shard_name            | citus_table_type | colocation_id | nodename  | nodeport | shard_size | schema_name | colocation_id | schema_size | schema_owner |
|----------------|---------|-----------------------|------------------|---------------|-----------|----------|------------|-------------|---------------|-------------|--------------|
| a.cities       | 102080  | a.cities_102080       | schema           | 4             | localhost | 9701     | 8192       | a           | 128           | kB          | citus        |
| a.map_tags     | 102145  | a.map_tags_102145     | schema           | 4             | localhost | 9701     | 32768      | a           | 128           | kB          | citus        |
| a.measurement  | 102047  | a.measurement_102047  | schema           | 4             | localhost | 9701     | 0          | a           | 128           | kB          | citus        |
| a.my_table     | 102179  | a.my_table_102179     | schema           | 4             | localhost | 9701     | 16384      | a           | 128           | kB          | citus        |
| a.people       | 102013  | a.people_102013       | schema           | 4             | localhost | 9701     | 32768      | a           | 128           | kB          | citus        |
| a.test         | 102008  | a.test_102008         | schema           | 4             | localhost | 9701     | 8192       | a           | 128           | kB          | citus        |
| a.widgets      | 102146  | a.widgets_102146      | schema           | 4             | localhost | 9701     | 32768      | a           | 128           | kB          | citus        |
| b.test         | 102009  | b.test_102009         | schema           | 5             | localhost | 9702     | 8192       | b           | 32            | kB          | citus        |
| b.test_col     | 102012  | b.test_col_102012     | schema           | 5             | localhost | 9702     | 24576      | b           | 32            | kB          | citus        |
| with_data.test | 102180  | with_data.test_102180 | schema           | 11            | localhost | 9702     | 647168     | with_data   | 632           | kB          | citus        |

### J.5.9.2.3. Finding the Distribution Column For a Table

Each distributed table in citus has a “distribution column”. For more information about what this is and how it works, see the [Choosing Distribution Column](#) section. There are many situations where it is important to know which column it is. Some operations require joining or filtering on the distribution column, and you may encounter error messages with hints like add a filter to the distribution column.

The `pg_dist_*` tables on the coordinator node contain diverse metadata about the distributed database. In particular the [pg\\_dist\\_partition](#) table holds information about the distribution column (formerly called *partition* column) for each table. You can use a convenient utility function to look up the distribution column name from the low-level details in the metadata. Here is an example and its output:

```
-- Create example table

CREATE TABLE products (
    store_id bigint,
    product_id bigint,
    name text,
    price money,

    CONSTRAINT products_pkey PRIMARY KEY (store_id, product_id)
);

-- Pick store_id as distribution column

SELECT create_distributed_table('products', 'store_id');

-- Get distribution column name for products table

SELECT column_to_column_name(logicalrelid, partkey) AS dist_col_name
FROM pg_dist_partition
WHERE logicalrelid='products'::regclass;
```

Example output:

|               |
|---------------|
| dist_col_name |
| store_id      |

#### J.5.9.2.4. Detecting Locks

This query will run across all worker nodes and identify locks, how long they have been open, and the offending queries:

```
SELECT * FROM citus_lock_waits;
```

For more information, see the [Distributed Query Activity](#) section.

#### J.5.9.2.5. Querying the Size of Your Shards

This query will provide you with the size of every shard of a given distributed table, designated here with the placeholder *my\_table*:

```
SELECT shardid, table_name, shard_size
FROM citus_shards
WHERE table_name = 'my_table';
```

Example output:

```
.
shardid | table_name | shard_size
-----+-----+-----
102170  | my_table  | 90177536
102171  | my_table  | 90177536
102172  | my_table  | 91226112
102173  | my_table  | 90177536
```

This query uses the [citus\\_shards](#) view.

#### J.5.9.2.6. Querying the Size of All Distributed Tables

This query gets a list of the sizes for each distributed table plus the size of their indices.

```
SELECT table_name, table_size
FROM citus_tables;
```

Example output:

| table_name    | table_size |
|---------------|------------|
| github_users  | 39 MB      |
| github_events | 98 MB      |

There are other ways to measure distributed table size as well. To learn more, see the [Determining Table and Relation Size](#) section.

#### J.5.9.2.7. Identifying Unused Indices

This query will run across all worker nodes and identify any unused indexes for a given distributed table, designated here with the placeholder *my\_distributed\_table*:

```
SELECT *
FROM run_command_on_shards('my_distributed_table', $cmd$
  SELECT array_agg(a) as infos
  FROM (
    SELECT (
      schemaname || '.' || relname || '##' || indexrelname || '##'
      || pg_size_pretty(pg_relation_size(i.indexrelid))::text
      || '##' || idx_scan::text
    ) AS a
    FROM pg_stat_user_indexes ui
    JOIN pg_index i
    ON ui.indexrelid = i.indexrelid
    WHERE NOT indisunique
    AND idx_scan < 50
    AND pg_relation_size(relid) > 5 * 8192
    AND (schemaname || '.' || relname)::regclass = '%s'::regclass
    ORDER BY
      pg_relation_size(i.indexrelid) / NULLIF(idx_scan, 0) DESC nulls first,
      pg_relation_size(i.indexrelid) DESC
    ) sub
  $cmd$);
```

Example output:

| shardid | success | result                                                                |
|---------|---------|-----------------------------------------------------------------------|
| 102008  | t       |                                                                       |
| 102009  | t       | {"public.my_distributed_table_102009##stupid_index_102009##28 MB##0"} |
| 102010  | t       |                                                                       |
| 102011  | t       |                                                                       |

#### J.5.9.2.8. Monitoring Client Connection Count

This query will give you the connection count by each type that are open on the coordinator:

```
SELECT state, count(*)
FROM pg_stat_activity
GROUP BY state;
```

Example output:

| state  | count |
|--------|-------|
| active | 3     |
| Ø      | 1     |

#### J.5.9.2.9. Viewing System Queries

##### J.5.9.2.9.1. Active Queries

The [citustat\\_activity](#) shows which queries are currently executing. You can filter to find the actively executing ones, along with the process ID of their backend:

```
SELECT global_pid, query, state
FROM citustat_activity
WHERE state != 'idle';
```

##### J.5.9.2.9.2. Why Are Queries Waiting

We can also query to see the most common reasons that non-idle queries that are waiting. For an explanation of the reasons, see the [Wait Event Types](#) table.

```
SELECT wait_event || ':' || wait_event_type AS type, count(*) AS number_of_occurrences
FROM pg_stat_activity
WHERE state != 'idle'
GROUP BY wait_event, wait_event_type
ORDER BY number_of_occurrences DESC;
```

Example output when executing the [pg\\_sleep](#) function in a separate query concurrently:

| type            | number_of_occurrences |
|-----------------|-----------------------|
| Ø               | 1                     |
| PgSleep:Timeout | 1                     |

#### J.5.9.2.10. Index Hit Rate

This query will provide you with your index hit rate across all nodes. Index hit rate is useful in determining how often indices are used when querying:

```
-- On coordinator
SELECT 100 * (sum(idx_blks_hit) - sum(idx_blks_read)) / sum(idx_blks_hit) AS
index_hit_rate
FROM pg_statio_user_indexes;

-- On workers
SELECT nodename, result as index_hit_rate
FROM run_command_on_workers($cmd$
SELECT 100 * (sum(idx_blks_hit) - sum(idx_blks_read)) / sum(idx_blks_hit) AS
index_hit_rate
```

```
FROM pg_statio_user_indexes;
$cmd$);
```

Example output:

| nodename  | index_hit_rate |
|-----------|----------------|
| 10.0.0.16 | 96.0           |
| 10.0.0.20 | 98.0           |

#### J.5.9.2.11. Cache Hit Rate

Most applications typically access a small fraction of their total data at once. Postgres Pro keeps frequently accessed data in memory to avoid slow reads from disk. You can see statistics about it in the [pg\\_statio\\_user\\_tables](#) view.

An important measurement is what percentage of data comes from the memory cache vs the disk in your workload:

```
-- On coordinator
SELECT
    sum(heap_blks_read) AS heap_read,
    sum(heap_blks_hit) AS heap_hit,
    100 * sum(heap_blks_hit) / (sum(heap_blks_hit) + sum(heap_blks_read)) AS
    cache_hit_rate
FROM
    pg_statio_user_tables;

-- On workers
SELECT nodename, result as cache_hit_rate
FROM run_command_on_workers($cmd$
    SELECT
        100 * sum(heap_blks_hit) / (sum(heap_blks_hit) + sum(heap_blks_read)) AS
        cache_hit_rate
    FROM
        pg_statio_user_tables;
$cmd$);
```

Example output:

| heap_read | heap_hit | cache_hit_rate      |
|-----------|----------|---------------------|
| 1         | 132      | 99.2481203007518796 |

If you find yourself with a ratio significantly lower than 99%, then you likely want to consider increasing the cache available to your database.

### J.5.9.3. Common Error Messages

#### J.5.9.3.1. could not connect to server: Connection refused

Caused when the coordinator node is unable to connect to a worker.

```
SELECT 1 FROM companies WHERE id = 2928;

ERROR:  connection to the remote node localhost:5432 failed with the following error:
could not connect to server: Connection refused
        Is the server running on host "localhost" (127.0.0.1) and accepting
```

TCP/IP connections on port 5432?

#### J.5.9.3.1.1. Resolution

To fix, check that the worker is accepting connections, and that DNS is correctly resolving.

#### J.5.9.3.2. canceling the transaction since it was involved in a distributed deadlock

Deadlocks can happen not only in a single-node database, but in a distributed database, caused by queries executing across multiple nodes. citus has the intelligence to recognize distributed deadlocks and defuse them by aborting one of the queries involved.

We can see this in action by distributing rows across worker nodes and then running two concurrent transactions with conflicting updates:

```
CREATE TABLE lockme (id int, x int);
SELECT create_distributed_table('lockme', 'id');

-- id=1 goes to one worker, and id=2 another
INSERT INTO lockme VALUES (1,1), (2,2);

----- TX 1 -----
BEGIN;

UPDATE lockme SET x = 3 WHERE id = 1;

UPDATE lockme SET x = 3 WHERE id = 2;

----- TX 2 -----
BEGIN;

UPDATE lockme SET x = 4 WHERE id = 2;

UPDATE lockme SET x = 4 WHERE id = 1;

ERROR:  canceling the transaction since it was involved in a distributed deadlock
```

#### J.5.9.3.2.1. Resolution

Detecting deadlocks and stopping them is part of normal distributed transaction handling. It allows an application to retry queries or take another course of action.

#### J.5.9.3.3. could not connect to server: Cannot assign requested address

```
WARNING:  connection error: localhost:9703
DETAIL:   could not connect to server: Cannot assign requested address
```

This occurs when there are no more sockets available by which the coordinator can respond to worker requests.

#### J.5.9.3.3.1. Resolution

Configure the operating system to re-use TCP sockets. Execute this on the shell in the coordinator node:

```
sysctl -w net.ipv4.tcp_tw_reuse=1
```

This allows reusing sockets in `TIME_WAIT` state for new connections when it is safe from a protocol viewpoint. Default value is 0 (disabled).

#### J.5.9.3.4. SSL error: certificate verify failed

In citus, nodes are required talk to one another using SSL by default. If SSL is not enabled on a Postgres Pro server when citus is first installed, the install process will enable it, which includes creating and self-signing an SSL certificate.

However, if a root certificate authority file exists (typically in `~/.postgresql/root.crt`), then the certificate will be checked unsuccessfully against that Certificate Authority at connection time.

#### J.5.9.3.4.1. Resolution

Possible solutions are to sign the certificate, turn off SSL, or remove the root certificate. Also a node may have trouble connecting to itself without the help of the `citus.local_hostname` configuration parameter.

#### **J.5.9.3.5.** could not connect to any active placements

When all available worker connection slots are in use, further connections will fail.

```
WARNING: connection error: hostname:5432
ERROR: could not connect to any active placements
```

##### **J.5.9.3.5.1. Resolution**

This error happens most often when copying data into citus in parallel. The `COPY` command opens up one connection per shard. If you run  $M$  concurrent copies into a destination with  $N$  shards, that will result in  $M*N$  connections. To solve the error, reduce the shard count of target distributed tables, or run fewer `\copy` commands in parallel.

#### **J.5.9.3.6.** remaining connection slots are reserved for non-replication superuser connections

This occurs when Postgres Pro runs out of available connections to serve concurrent client requests.

##### **J.5.9.3.6.1. Resolution**

The `max_connections` configuration parameter adjusts the limit, with a typical default of 100 connections. Note that each connection consumes resources, so adjust sensibly. When increasing `max_connections` it is usually a good idea to increase `memory limits` too.

Using `pgbouncer` can also help by queueing connection requests, which exceed the connection limit.

#### **J.5.9.3.7.** pgbouncer cannot connect to server

In a self-hosted citus cluster, this error indicates that the coordinator node is not responding to `pgbouncer`.

##### **J.5.9.3.7.1. Resolution**

Try connecting directly to the server with `psql` to ensure it is running and accepting connections.

#### **J.5.9.3.8.** creating unique indexes on non-partition columns is currently unsupported

As a distributed system, citus can guarantee uniqueness only if a unique index or primary key constraint includes a table distribution column. That is because the shards are split so that each shard contains non-overlapping partition column values. The index on each worker node can locally enforce its part of the constraint.

Trying to make a unique index on a non-distribution column will generate an error:

```
ERROR: creating unique indexes on non-partition columns is currently unsupported

Enforcing uniqueness on a non-distribution column would require citus to check every shard on every INSERT to validate, which defeats the goal of scalability.
```

##### **J.5.9.3.8.1. Resolution**

There are two ways to enforce uniqueness on a non-distribution column:

1. Create a composite unique index or primary key that includes the desired column ( $C$ ), but also includes the distribution column ( $D$ ). This is not quite as strong a condition as uniqueness on  $C$  alone, but will ensure that the values of  $C$  are unique for each value of  $D$ . For instance if distributing by `company_id` in a multi-tenant system, this approach would make  $C$  unique within each company.
2. Use a [reference table](#) rather than a hash-distributed table. This is only suitable for small tables, since the contents of the reference table will be duplicated on all nodes.

#### **J.5.9.3.9.** function create\_distributed\_table does not exist

```
SELECT create_distributed_table('foo', 'id');
/*
ERROR: function create_distributed_table(unknown, unknown) does not exist
LINE 1: SELECT create_distributed_table('foo', 'id');
```

HINT: No function matches the given name and argument types. You might need to add explicit type casts.  
\*/

#### J.5.9.3.9.1. Resolution

When basic [utility functions](#) are not available, check whether the citus extension is properly installed. Running `\dx` in psql will list installed extensions.

One way to end up without extensions is by creating a new database in a Postgres Pro server, which requires extensions to be re-installed. See the [Creating a New Database](#) section to learn how to do it right.

#### J.5.9.3.10. STABLE functions used in UPDATE queries cannot be called with column references

Each Postgres Pro function has a [volatility](#) classification, which indicates whether the function can update the database and whether the function's return value can vary over time given the same inputs. A `STABLE` function is guaranteed to return the same results given the same arguments for all rows within a single statement, while an `IMMUTABLE` function is guaranteed to return the same results given the same arguments forever.

Non-immutable functions can be inconvenient in distributed systems because they can introduce subtle changes when run at slightly different times across shards. Differences in database configuration across nodes can also interact harmfully with non-immutable functions.

One of the most common ways this can happen is using the `timestamp` in Postgres Pro, which unlike `timestampz` does not keep a record of time zone. Interpreting a `timestamp` column makes reference to the database timezone, which can be changed between queries, hence functions operating on timestamps are not immutable.

citus forbids running distributed queries that filter results using stable functions on columns. For instance:

```
-- foo_timestamp is timestamp, not timestampz
UPDATE foo SET ... WHERE foo_timestamp < now();
```

ERROR: STABLE functions used in UPDATE queries cannot be called with column references

In this case the comparison operator `<` between `timestamp` and `timestampz` is not immutable.

##### J.5.9.3.10.1. Resolution

Avoid stable functions on columns in a distributed `UPDATE` statement. In particular, whenever working with times use `timestampz` rather than `timestamp`. Having a time zone in `timestampz` makes calculations immutable.

## J.5.10. Frequently Asked Questions

### J.5.10.1. Can I create primary keys on distributed tables?

Currently citus imposes primary key constraint only if the distribution column is a part of the primary key. This assures that the constraint needs to be checked only on one shard to ensure uniqueness.

### J.5.10.2. How do I add nodes to an existing citus cluster?

With citus, you can add nodes manually by calling the [citus\\_add\\_node](#) function with the hostname (or IP address) and port number of the new node.

After adding a node to an existing cluster, the new node will not contain any data (shards). citus will start assigning any newly created shards to this node. To rebalance existing shards from the older nodes to the new node, citus provides an open source shard rebalancer utility. You can find more information in the [Rebalancing Shards Without Downtime](#) section.

### J.5.10.3. How does citus handle failure of a worker node?

citus uses Postgres Pro streaming replication to replicate the entire worker-node as-is. It replicates worker nodes by continuously streaming their WAL records to a standby. You can configure streaming replication on-premise yourself by consulting the [Streaming Replication](#) section.

### J.5.10.4. How does citus handle failover of the coordinator node?

As the citus coordinator node is similar to a standard Postgres Pro server, regular Postgres Pro synchronous replication and failover can be used to provide higher availability of the coordinator node. To learn more about handling coordinator node failures, see the [Coordinator Node Failures](#) section.

### J.5.10.5. Are there any Postgres Pro features not supported by citus?

Since citus provides distributed functionality by extending Postgres Pro, it uses the standard Postgres Pro SQL constructs. The vast majority of queries are supported, even when they combine data across the network from multiple database nodes. This includes transactional semantics across nodes. For an up-to-date list of SQL coverage, see the [Limitations](#) section.

What's more, citus has 100% SQL support for queries that access a single node in the database cluster. These queries are common, for instance, in multi-tenant applications where different nodes store different tenants. To learn more, see the [When to Use citus](#) section.

Remember that even with this extensive SQL coverage data modeling can have a significant impact on query performance. See the [Query Processing](#) section for details on how citus executes queries.

### J.5.10.6. How do I choose the shard count when I hash-partition my data?

One of the choices when first distributing a table is its shard count. This setting can be set differently for each co-location group, and the optimal value depends on the use case. It is possible, but difficult, to change the count after cluster creation, so use these guidelines to choose the right size.

In the [multi-tenant SaaS database](#) use case we recommend choosing between 32 and 128 shards. For smaller workloads, say <100GB, you could start with 32 shards and for larger workloads you could choose 64 or 128. This means that you have the leeway to scale from 32 to 128 worker machines.

In the [real-time analytics](#) use case, shard count should be related to the total number of cores on the workers. To ensure maximum parallelism, you should create enough shards on each node such that there is at least one shard per CPU core. We typically recommend creating a high number of initial shards, e.g. 2x or 4x the number of current CPU cores. This allows for future scaling if you add more workers and CPU cores.

To choose a shard count for a table you wish to distribute, update the [citus.shard\\_count](#) configuration parameter. This affects subsequent calls to the [create\\_distributed\\_table](#) function. For example:

```
SET citus.shard_count = 64;
-- any tables distributed at this point will have
-- sixty-four shards
```

For more guidance on this topic, see the [Choosing Cluster Size](#) section.

### J.5.10.7. How do I change the shard count for a hash-partitioned table?

citus has a function called [alter\\_distributed\\_table](#) that can change the shard count of a distributed table.

### J.5.10.8. How does citus support count (distinct) queries?

citus can evaluate `count (distinct)` aggregates both in and across worker nodes. When aggregating on a table's distribution column, citus can push the counting down inside worker nodes and total the results. Otherwise it can pull distinct rows to the coordinator and calculate there. If transferring data to the coordinator is too expensive, fast approximate counts are also available. More details in [The count \(distinct\) Aggregates](#) section.

#### J.5.10.9. In which situations are uniqueness constraints supported on distributed tables?

citus is able to enforce a primary key or uniqueness constraint only when the constrained columns contain the distribution column. In particular this means that if a single column constitutes the primary key then it has to be the distribution column as well.

This restriction allows citus to localize a uniqueness check to a single shard and let Postgres Pro on the worker node do the check efficiently.

#### J.5.10.10. How do I create database roles, functions, extensions etc in a citus cluster?

Certain commands, when run on the coordinator node, do not get propagated to the workers:

- CREATE ROLE/USER
- CREATE DATABASE
- ALTER ... SET SCHEMA
- ALTER TABLE ALL IN TABLESPACE
- CREATE TABLE (see the [Table Types](#) section)

For the other types of objects above, create them explicitly on all nodes. citus provides a function to execute queries across all workers:

```
SELECT run_command_on_workers($cmd$
/* the command to run */
CREATE ROLE ...
$cmd$);
```

Learn more in the [Manual Query Propagation](#) section. Also note that even after manually propagating CREATE DATABASE, citus must still be installed there. See the [Creating a New Database](#) section.

In the future citus will automatically propagate more kinds of objects. The advantage of automatic propagation is that citus will automatically create a copy on any newly added worker nodes (see the [citus.pg\\_dist\\_object](#) table to learn more).

#### J.5.10.11. What if a worker node's address changes?

If the hostname or IP address of a worker changes, you need to let the coordinator know using the [citus\\_update\\_node](#) function:

```
-- Update worker node metadata on the coordinator
-- (remember to replace 'old-address' and 'new-address'
-- with the actual values for your situation)

SELECT citus_update_node(nodeid, 'new-address', nodeport)
FROM pg_dist_node
WHERE nodename = 'old-address';
```

Until you execute this update, the coordinator will not be able to communicate with that worker for queries.

#### J.5.10.12. Which shard contains data for a particular tenant?

citus provides utility functions and metadata tables to determine the mapping of a distribution column value to a particular shard, and the shard placement on a worker node. See the [Finding Which Shard Contains Data For a Specific Tenant](#) section for more details.

#### J.5.10.13. I forgot the distribution column of a table, how do I find it?

The citus coordinator node metadata tables contain this information. See the [Finding the Distribution Column For a Table](#) section.

#### J.5.10.14. Can I distribute a table by multiple keys?

No, you must choose a single column per table as the distribution column. A common scenario where people want to distribute by two columns is for timeseries data. However, for this case we recommend using a hash distribution on a non-time column, and combining this with Postgres Pro partitioning on the time column, as described in the [Timeseries Data](#) section.

#### J.5.10.15. Why does `pg_relation_size` report zero bytes for a distributed table?

The data in distributed tables lives on the worker nodes (in shards), not on the coordinator. A true measure of distributed table size is obtained as a sum of shard sizes. citus provides helper functions to query this information. See the [Determining Table and Relation Size](#) section to learn more.

#### J.5.10.16. Why am I seeing an error about `citus.max_intermediate_result_size`?

citus has to use more than one step to run some queries having subqueries or CTEs. Using the [subquery/CTE push-pull execution](#), it pushes subquery results to all worker nodes for use by the main query. If these results are too large, this might cause unacceptable network overhead, or even insufficient storage space on the coordinator node which accumulates and distributes the results.

citus has a configurable setting [citus.max\\_intermediate\\_result\\_size](#) to specify a subquery result size threshold at which the query will be canceled. If you run into the error, it looks like:

```
ERROR: the intermediate result size exceeds citus.max_intermediate_result_size
        (currently 1 GB)
DETAIL: Citus restricts the size of intermediate results of complex subqueries and
        CTEs to avoid accidentally pulling large result sets into once place.
HINT: To run the current query, set citus.max_intermediate_result_size to a higher
        value or -1 to disable.
```

As the error message suggests, you can (cautiously) increase this limit by altering the variable:

```
SET citus.max_intermediate_result_size = '3GB';
```

#### J.5.10.17. Can I shard by schema on citus for multi-tenant applications?

Yes, [schema-based sharding](#) is available.

#### J.5.10.18. How does `cstore_fdw` work with citus?

The `cstore_fdw` extension is no longer needed on Postgres Pro 12 and above, because [columnar storage](#) is now implemented directly in citus. Unlike `cstore_fdw`, columnar tables of the citus support transactional semantics, replication, and [pg\\_upgrade](#). citus query parallelization, seamless sharding, and high-availability benefits combine powerfully with the superior compression and I/O utilization of columnar storage for large dataset archival and reporting.

---

# Appendix K. Configuring Postgres Pro for 1C Solutions

You can install and use Postgres Pro with 1C solutions in a client/server model.

Make sure that the Russian locale (such as `ru_RU.UTF-8` on Linux systems) is installed and that it is the active locale of the user who creates the database cluster. For example, for Debian systems do the following:

```
sudo dpkg-reconfigure locales # Choose locale ru_RU.UTF-8 to generate
export LANG="ru_RU.UTF-8"
/opt/pgpro/ent-16/bin/pg-setup initdb
```

For more details, see related sections of the documentation for your operating system and for 1C.

Also, for optimal performance and stability, modify the following settings in the `postgresql.conf` configuration file of Postgres Pro server:

1. Increase the maximum number of allowed concurrent connections to the database server, up to 1000 connections. 1C solutions can open a large number of connections, even if not all of them are used, so it is recommended to allow not less than 500 connections.

```
max_connections = 1000
```

2. To ensure that temporary tables are handled correctly, modify the following parameters:

- Increase the buffer size for temporary tables:

```
temp_buffers = 32MB
```

- Increase the number of allowed locks of tables or indexes per transaction to 256:

```
max_locks_per_transaction = 256
```

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail, leaving multiple orphaned temporary tables.

3. Enable backslash escapes in all strings, and switch off the warning about using the backslash escape symbol:

```
standard_conforming_strings = off
escape_string_warning = off
```

4. Set the `effective_cache_size` parameter to at least half of RAM available on the system. Postgres Pro query optimizer performance depends on the amount of allocated RAM.

5. To use the logical replication mechanism of the `dbcopies_decoding` module, `wal_level` must be set to `logical`.

6. Optimize query planning using `plantuner` extension, as follows:

- Add `plantuner` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'plantuner'
```

- Tune Postgres Pro optimizer to improve planning for recently created empty tables:

```
plantuner.fix_empty_table = 'on'
```

---

# Appendix L. Migration Tools in Postgres Pro

Postgres Pro provides tools that can be useful when migrating from Oracle to Postgres Pro in addition to [native support](#).

## L.1. Working with Packages

Postgres Pro provides packages, which are similar to packages in Oracle, and can be useful when [porting](#) from PL/SQL to PL/pgSQL. This section explains differences between Postgres Pro's and Oracle's packages.

In Oracle, a package is a schema object that groups logically related types, global variables, and subprograms (procedures and functions). A package consists of a package specification and a package body (in general, the package body is optional). In the package specification, those items are declared that can be referenced from outside the package and used in applications: types, variables, constants, exceptions, cursors, and subprograms. The package body contains package subprogram implementation, private variable declarations, and the initialization section. The variables, types and subprograms declared in the package body cannot be used from outside the package.

The example below shows the package specification of the PL/SQL `counter` package in Oracle, which contains the global variable `n` and the function `inc`:

```
CREATE PACKAGE counter IS
    n int;

    FUNCTION inc RETURN int;
END;
```

The function `inc` and the global variable `k` (available only in the package body) are declared in the `counter` package body in Oracle.

```
CREATE PACKAGE BODY counter IS
    k int := 3; -- the variable is available only in the package body

    FUNCTION inc RETURN int IS
    BEGIN
        n := n + 1;
        RETURN n;
    END;

    -- Package initialization
    BEGIN
        n := 1;
        FOR i IN 1..10 LOOP
            n := n + n;
        END LOOP;
    END;
```

Global package variables exist during the session lifetime. Note that the package body contains the initialization section — the code block executed once a session when any package element is accessed for the first time. In Oracle, package elements could be accessed using dot notation as follows: `package_name.package_element`.

```
SET SERVEROUTPUT ON

BEGIN
```

```

    dbms_output.put_line(counter.n);
    dbms_output.put_line(counter.inc());
END;
/

1024
1025

```

A package in Postgres Pro is essentially a schema that contains the initialization function and may contain only functions, procedures and composite types. The initialization function is a PL/pgSQL function named `__init__` that has no arguments and returns `void`. The initialization function must be defined before any other package function. By default, all the variables declared in the package initialization function, package functions and package procedures are public, so they can be called using dot notation from outside the package by other functions, procedures and anonymous blocks that import the package. The `#private` modifier defines functions and procedures as private, and the `#export` modifier defines which package variables are public. For example, the `bar` variable declared in the `__init__` function of the `foo` package can be referenced as `foo.bar`.

Package variables can be accessed only from PL/pgSQL code. To retrieve the value of the global variable in an SQL query (`SELECT`) or in a DML operation (`INSERT`, `UPDATE`, `DELETE`), add a getter function that returns the value to the caller. For package variables declared as constant, default definition syntax in PL/pgSQL is used. The package initialization function is invoked automatically when any of the following elements is accessed in the current session:

- Any function in this package with the `#package` modifier
- Code block (anonymous or a function) importing this package

The initialization function can be invoked manually to reset values of package variables. To do that, you can also use a built-in function `plpgsql_reset_packages()` but it resets all the packages in the current session (similar to `DBMS_SESSION.RESET_PACKAGES` in Oracle).

The above example of the Oracle's `counter` package after porting to Postgres Pro will look like this:

```

CREATE PACKAGE counter

CREATE FUNCTION __init__() RETURNS void AS $$ -- package initialization
#export n
DECLARE
    n int := 1; -- n public variable, available both inside and outside the package
    k int := 3; -- k private variable, only available inside the package
BEGIN
    FOR i IN 1..10 LOOP
        n := n + n;
    END LOOP;
END;
$$

CREATE FUNCTION inc() RETURNS int AS $$
BEGIN
    n := n + 1;
    RETURN n;
END;
$$
;

```

You can use this package in Postgres Pro as follows:

```

DO $$
#import counter
BEGIN

```

```
RAISE NOTICE '%', counter.n;
RAISE NOTICE '%', counter.inc();
END;
$$;
```

```
NOTICE: 1024
NOTICE: 1025
```

There are some points worth noting.

- Schemas cannot contain packages, as the package itself is a schema.
- The package name must be distinct from the name of any existing package or schema in the current database.
- A package may contain only composite types, global variables, procedures, and functions (for example, tables, views, sequences *cannot* be created in packages).
- All package variables are public if the `#export` modifier is used or if there is no `#export` modifier at all. All the package functions and procedures are public unless the `#private` modifier is used. Public package variables are available from any code block importing the package.
- Package specification and package body are *not* defined separately.
- Package functions and code blocks importing them must be written in PL/pgSQL.
- All package elements must be accessed from outside the package using qualified names, i.e. using package name. From inside the package, functions can access them directly.
- Global package variables can be initialized when declared:

```
DECLARE x int := 42;
```

or later in the initialization function `__init__`. For the external code using the package, it doesn't matter.

- Types must be declared in the beginning of the package before the first subprogram.
- The `__init__` function must be the first subprogram defined in the package.

To support packages in Postgres Pro, the following enhancements were introduced:

- [Function modifiers](#)
- [Built-in functions](#)
- `CREATE [OR REPLACE] PACKAGE` and `DROP PACKAGE` [SQL commands](#)

### L.1.1.1. Function and Variable Modifiers

Function and variable modifiers start with `#` and are placed between the name and the `DECLARE` statement (see example below).

#### L.1.1.1.1. `#package` Modifier

The modifier `#package` indicates that the function should be treated as a package function, which means the following:

- When the function is called, the package is initialized automatically if it hasn't been initialized in the current session.
- The function can access the variables of its package directly.

The `__init__` function must not contain the `#package` modifier. A function with the `#package` modifier can be created only in a schema that already contains the `__init__` function (that is, in a package). If you create a function within the `CREATE OR REPLACE PACKAGE`, the `#package` modifier may be omitted as it is added automatically in this command.

#### L.1.1.2. #import Modifier

The modifier `#import` indicates that the function is supposed to work with variables of an outside package (or a number of packages). This is called package import and means the following:

- When this function is accessed, the imported package is initialized automatically if it hasn't been initialized in the current session.
- The function can access the variables of the imported package using package name. To import the package, use the following syntax:

```
#import packages_list
```

Here `packages_list` is the list of imported package names. You can also import packages separately, for example:

```
#import foo, bar
```

would mean the same as:

```
#import foo  
#import bar
```

All the packages imported in the `__init__` function are automatically imported for other functions of the package.

In the below example of using the `#import` modifier, the `showValues` procedure calls `p` of the `http` package and `set_action` of the `dbms_application_info` package.

```
CREATE OR REPLACE PROCEDURE showValues(p_Str varchar) AS $$  
#import http, dbms_application_info  
BEGIN  
    CALL dbms_application_info.set_action('Show hello');  
  
    CALL http.p('<p>' || p_Str || '</p>');  
END;  
$$LANGUAGE plpgsql;
```

#### L.1.1.3. #private Modifier

The `#private` modifier indicates that the function is private, meaning that it is only available inside the package and cannot be referenced from outside it. Private functions are necessary for the internal processes of the package. They are only available in the package that specifies them.

#### L.1.1.4. #export Modifier

The modifier `#export` indicates that the package variable is public, meaning it can be referenced from outside the package. The `#export` modifier is used when initializing a package:

```
#export var_name_1, var_name_2, ... var_name_N
```

- If the package does not contain the `#export` modifier, all the package variables are public. The same result is achieved with the `#export on` modifier.
- If the package contains the `#export` modifier with specified variables, these variables are public, while all other package variables are private.
- The `#export` modifier can be used several times in the `__init__` function, and all the specified variables are considered public.
- The `#export off` modifier means no variables should be public, and specifying exported variables in this case will result in error.
- The `#export on` modifier renders all the variables public, and using the `#export` modifier again will result in error.

- The `#export` modifier must contain at least one variable.
- Private variables can only be used inside the package that specifies them. They can be called from functions and procedures from the package with the `#package` modifier. If they are declared separately, the package name must be specified.
- Public variables can be used both inside and outside the package in case functions, procedures and anonymous blocks have the `#import` modifier that specifies the package name.

### L.1.1.2. Built-in Functions

PL/pgSQL provides a built-in function `plpgsql_reset_packages()` that deinstantiates all the packages in this session to bring the session to the original state.

```
SELECT plpgsql_reset_packages();
```

### L.1.1.3. SQL Commands

You can work with packages using regular schema-oriented commands (like `CREATE SCHEMA` and `DROP SCHEMA`) with function modifiers but `CREATE OR REPLACE PACKAGE` and `DROP PACKAGE` commands are more convenient.

#### L.1.1.3.1. CREATE OR REPLACE PACKAGE

`CREATE OR REPLACE PACKAGE` will either create a new package, or replace the existing definition.

```
CREATE [OR REPLACE] PACKAGE package_name package_body;
```

Here *package\_name* is the name of the schema, and *package\_body* is the set of package creation commands with several caveats to be aware of:

- The `CREATE SCHEMA` is executed automatically.
- The `#package` modifier can be omitted — all the functions are modified automatically.
- No language is specified when creating functions.
- Function and type names are specified without the package name.
- The individual top-level subcommands in the package body do not end with semicolons.
- The package name must be distinct from the name of any existing package or schema in the current database.

The example below shows how the package can be created using the `CREATE SCHEMA` command.

```
CREATE SCHEMA foo;
CREATE TYPE foo.footype AS (a int, b int);
CREATE FUNCTION foo.__init__() RETURNS void AS $$
DECLARE x int := 1;
BEGIN
    RAISE NOTICE 'foo initialized';
END;
$$ LANGUAGE plpgsql;

CREATE FUNCTION foo.get() RETURNS int AS $$
#package
BEGIN
    RETURN x;
END;
$$ LANGUAGE plpgsql;

CREATE FUNCTION foo.inc() returns void AS $$
#package
BEGIN
```

```
x := x + 1;
END;
$$ LANGUAGE plpgsql;
```

The following is an equivalent way of achieving the same result using the `CREATE PACKAGE` command:

```
CREATE PACKAGE foo
  CREATE TYPE footype AS (a int, b int)

  CREATE FUNCTION __init__() RETURNS void AS $$
  DECLARE
    x int := 1;
  BEGIN
    RAISE NOTICE 'foo initialized';
  END;
  $$

  CREATE FUNCTION get() RETURNS int AS $$
  BEGIN
    RETURN x;
  END;
  $$

  CREATE FUNCTION inc() RETURNS void AS $$
  BEGIN
    x := x + 1;
  END;
  $$
;
```

You can replace the existing package with the following special considerations:

- You can use the `CREATE OR REPLACE PACKAGE` to replace only schemas that are packages (i.e. containing only functions and composite types and the initialization function).
- When any elements of the old package are not defined in the new package, they are dropped if there are no dependent objects, otherwise the `CREATE OR REPLACE PACKAGE` is forced to fail.
- If you replace the package without changing the function signature, its body is replaced, while dependent objects still remain. If the function signature changes, you would actually be creating a new, distinct function. The latter would only work when there are no dependent objects, otherwise the `CREATE OR REPLACE PACKAGE` is forced to fail.
- The same restriction applies to replacing types.
- If the command fails due to existing dependent objects, the containing package is referenced by the error rather than the objects themselves.

`CREATE OR REPLACE PACKAGE` is a fully transactional command so any mistakes when defining package elements would cause it to fail entirely, and all the changes are discarded.

### L.1.3.2. DROP PACKAGE

`DROP PACKAGE` removes packages (schemas) from the database along with dependent objects.

```
DROP PACKAGE [IF EXISTS] package_name_list [CASCADE];
```

Here *package\_name\_list* is the list of packages to be dropped. The command is fully transactional so either all of the packages are dropped, or none if the command fails. This command is similar to `DROP SCHEMA` with several caveats to be aware of:

- You can use `DROP PACKAGE` to drop only schemas that are packages (i.e. containing only functions and composite types and the initialization function).

- If the command fails due to existing dependent objects, the containing package is referenced by the error rather than the objects themselves.
- Using the `CASCADE` option might make the command find objects to be removed in other packages besides the one(s) named. In this case, other packages are dropped as well.

All the dependencies mentioned in this section are standard Postgres Pro dependencies (see [Section 5.14](#)). For example, if a function uses other function signature in its own definition, the dependency is created but a single function call does not create one. When a function accesses package variables from outside the package, no dependency is created either (even a getter function).

### L.1.4. Limitations

- In Oracle, a package is an atomic structure that can be modified only as a whole with `CREATE OR REPLACE`. As far as Postgres Pro Enterprise is concerned, a package is a schema so its elements can be modified separately with `CREATE OR REPLACE PROCEDURE`, `CREATE OR REPLACE FUNCTION`, or `ALTER TYPE`. Thus, you can easily replace a function or a type that does not have dependencies rather than replace the package itself. If you replace the package, you also need to replace all the dependent packages and functions manually.
- Since a package in Postgres Pro is a schema, the user should have the rights on the schema:

```
GRANT USAGE ON SCHEMA foo, bar TO hr_user;
```

If the package must be run with definer's rights, the user should have all the rights on the schema:

```
GRANT ALL ON SCHEMA hr_main TO hr_user;
```

If the package must be run with invoker's rights, the user should have specific rights on tables and views to be used in the package, for example:

```
GRANT SELECT demo.employee_tab TO hr_user;
```

- Unlike Oracle, which stores all the information about package dependencies and in general about all PL/SQL objects (triggers, functions, procedures, etc.), Postgres Pro doesn't store dependencies at the level of function body and variables so these dependencies cannot be tracked when the package changes.
- In Oracle, when the dependencies are broken, the package becomes `INVALID`. In this case, the package still exists in the database but it is not working. Unlike that, in Postgres Pro any object created or modified in the database must be valid. So if any operation in Postgres Pro leads to package invalidation (for example, the table used in package type declaration is dropped), it cannot be executed — first, the package must be deleted as it cannot remain invalid in the database.
- When modifying packages, make sure that no other sessions use them (which can be done by stopping the application before replacing the packages). Once done, restart the application, and updated package versions will be available in all the sessions. This limitation is caused by the lack of library cache in Postgres Pro (unlike Oracle) since each backend caches PL/pgSQL code. If the package is modified in one session, and another session still works with the old package version, it would cause inconsistency, especially if the list of global package variables changes. Currently there are no global locks for package modification (like latch in Oracle) and no package modification tracking (like “ORA-04068: existing state of packages has been discarded” in Oracle).
- Unlike Oracle, packages are not separated into specification and body.
- Clauses modifying procedure declaration (like `RESULT_CACHE`, `DETERMINISTIC` in Oracle) are not supported. PL/SQL compiler directives are not supported either (like `INLINE pragma`, `UDF pragma`, etc.).

## L.2. Package Export Using ora2pgpro

[ora2pgpro](#) is a utility based on the ora2pg application, which can be used for porting Oracle packages and autonomous transactions as Postgres Pro [packages](#) and [autonomous transactions](#) when migrating an Oracle database to a Postgres Pro-compatible schema. ora2pgpro properly extracts type and variable declarations from the package body and specification, including the initialization section. Moreover,

ora2pgpro exports autonomous transactions directly as opposed to ora2pg's translation of autonomous transactions into wrapper functions using dblink or pg\_background extensions. It's worth noting that autonomous transactions are syntactically very different in Oracle and Postgres Pro. Currently, circular dependencies of packages are not supported.

To export packages using ora2pgpro, first edit the ora2pgpro.conf file.

- Configure settings to control the access to the Oracle database.

```
ORACLE_HOME "my_oracle_home_dir"
ORACLE_DSN dbi:Oracle:host=localhost;sid=MY_SID;port=1521
ORACLE_USER USER
ORACLE_PWD PASSWORD
SCHEMA SCHEMA
```

- Optionally, you can set the TYPE variable to PACKAGE. Note that you can also set the type of export when running ora2pgpro as shown in the example below.
- If you want to export autonomous transactions directly as Postgres Pro Enterprise autonomous transactions, set POSTGRESPRO\_ATX to 1. Note that this disables the AUTONOMOUS\_TRANSACTION parameter responsible for translation of autonomous transactions into a wrapper function.

```
POSTGRESPRO_ATX 1
```

- If you want to export only some packages, list them separated by commas in the INCLUDE\_PACKAGES parameter, or specify the unwanted packages names in the EXCLUDE\_PACKAGES parameter.

```
INCLUDE_PACKAGES 'PKG_A', 'PKG_B'
```

Now you can run ora2pgpro.

```
ora2pgpro -t PACKAGE -c ora2pgpro.conf -o packages.sql
```

A short example below shows how the CUSTOMER\_PKG package can be ported using ora2pgpro. This is the Oracle version:

```
CREATE OR REPLACE PACKAGE customer_pkg IS

    gBatchSize constant integer := 100;

    type
        TCustomerInfo is record
        (
            Id            number(9,0),
            Name          varchar2(32 char),
            Description    varchar2(512 char)
        );

    type
        TBuffer is table of TCustomerInfo index by pls_integer;
    v_gBuffer TBuffer;

    v_cMainCustomer constant number(9,0) := 1;

    v_gCurrentCustomerId number(9,0);

    ...

    PROCEDURE dump(v_pCustomer in out nocopy TCustomerInfo);

    PROCEDURE init_package;
END;
```

```
CREATE OR REPLACE PACKAGE BODY customer_pkg IS

...

PROCEDURE dump(v_pCustomer in out nocopy TCustomerInfo) IS
BEGIN
    console.log('----- Dump of customer_pkg.TCustomerInfo
-----');
    console.log('Id          => ' || v_pCustomer.Id);
    console.log('Name        => ' || v_pCustomer.Name);
    console.log('Description => ' || v_pCustomer.Description);

console.log('-----');
END;

PROCEDURE init_package IS
BEGIN
    v_gCurrentCustomerId := 0;
END;

BEGIN
    init_package();
END;
```

Here is how this package would end up in Postgres Pro:

```
-- Oracle package 'CUSTOMER_PKG' declaration, edit to match PostgreSQL syntax

DROP SCHEMA IF EXISTS customer_pkg CASCADE;
CREATE SCHEMA IF NOT EXISTS customer_pkg;
CREATE TYPE customer_pkg.tcustomerinfo AS (
    Id          integer,
    Name        varchar(32),
    Description varchar(512)
);

CREATE TYPE customer_pkg.tbuffer AS (tbuffer CUSTOMER_PKG.TCustomerInfo[]);

CREATE OR REPLACE FUNCTION customer_pkg.__init__ () RETURNS VOID AS $body$
#import CONSOLE
DECLARE

    gBatchSize constant integer := 100;
    v_gBuffer CUSTOMER_PKG.TBuffer;
    v_cMainCustomer constant integer := 1;
    v_gCurrentCustomerId integer;

BEGIN
    CALL customer_pkg.init_package();
end;

$body$
LANGUAGE PLPGSQL
SECURITY DEFINER
;
-- REVOKE ALL ON FUNCTION customer_pkg.__init__ () FROM PUBLIC;
```

```

CREATE OR REPLACE PROCEDURE customer_pkg.init_package () AS $body$
#package
BEGIN
    v_gCurrentCustomerId := 0;
end;
$body$
LANGUAGE PLPGSQL
SECURITY DEFINER
;
-- REVOKE ALL ON PROCEDURE customer_pkg.init_package () FROM PUBLIC;

CREATE OR REPLACE PROCEDURE customer_pkg.dump (v_pCustomer INOUT
CUSTOMER_PKG.TCustomerInfo) AS $body$
#package
BEGIN
    CALL console.log('----- Dump of customer_pkg.TCustomerInfo
-----');
    CALL console.log('Id          => ' || v_pCustomer.Id);
    CALL console.log('Name        => ' || v_pCustomer.Name);
    CALL console.log('Description => ' || v_pCustomer.Description);
    CALL
console.log('-----');
end;
$body$
LANGUAGE PLPGSQL
SECURITY DEFINER
;
-- REVOKE ALL ON PROCEDURE customer_pkg.dump (v_pCustomer INOUT
CUSTOMER_PKG.TCustomerInfo) FROM PUBLIC;

```

Complete package examples are available at [ora2pgpro.postgrespro.ru](https://ora2pgpro.postgrespro.ru). The scripts are distributed under the [PostgreSQL license](#). See also the [ora2pgpro documentation](#).

## L.3. Script Parameters

Postgres Pro provides the ability to pass named and positional parameters for script execution. For more information, see the `\i` command on the [psql](#) reference page.

# Appendix M. Postgres Pro Limits

[Table M.1](#) describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

**Table M.1. Postgres Pro Limitations**

| Item                    | Upper Limit                                                           | Comment                                                                |
|-------------------------|-----------------------------------------------------------------------|------------------------------------------------------------------------|
| database size           | unlimited                                                             |                                                                        |
| number of databases     | 4,294,950,911                                                         |                                                                        |
| relations per database  | 1,431,650,303                                                         |                                                                        |
| relation size           | 32 TB                                                                 | with the default <code>BLCKSZ</code> of 8192 bytes                     |
| rows per table          | limited by the number of tuples that can fit onto 4,294,967,295 pages |                                                                        |
| columns per table       | 1,600                                                                 | further limited by tuple size fitting on a single page; see note below |
| columns in a result set | 1,664                                                                 |                                                                        |
| field size              | 1 GB                                                                  |                                                                        |
| indexes per table       | unlimited                                                             | constrained by maximum relations per database                          |
| columns per index       | 32                                                                    | can be increased by recompiling Postgres Pro                           |
| partition keys          | 32                                                                    | can be increased by recompiling Postgres Pro                           |
| identifier length       | 63 bytes                                                              | can be increased by recompiling Postgres Pro                           |
| function arguments      | 100                                                                   | can be increased by recompiling Postgres Pro                           |
| query parameters        | 65,535                                                                |                                                                        |

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Each table can store a theoretical maximum of  $2^{32}$  out-of-line values; see [Section 74.2](#) for a detailed discussion of out-of-line storage. This limit arises from the use of a 32-bit OID to identify each such value. The practical limit is significantly less than the theoretical limit, because as the OID space fills up, finding an OID that is still free can become expensive, in turn slowing down INSERT/UPDATE statements. Typically, this is only an issue for tables containing many terabytes of data; partitioning is a possible workaround.

# Appendix N. Demo Database “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section N.1](#) for details.

**Figure N.1. Airlines in Russia**

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the [PostgreSQL license](#).

You can send us your feedback to [edu@postgrespro.ru](mailto:edu@postgrespro.ru).

## N.1. Installation

The demo database is available at [edu.postgrespro.com](http://edu.postgrespro.com) in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is about 300 MB)
- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is about 700 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of `psql`:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

## N.2. Schema Diagram

**Figure N.2. Bookings Schema Diagram**

## N.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

## N.4. Schema Objects

### N.4.1. List of Relations

| Name                         | Type  | Small | Medium | Big    | Description             |
|------------------------------|-------|-------|--------|--------|-------------------------|
| <code>aircrafts</code>       | view  |       |        |        | Aircraft                |
| <code>aircrafts_data</code>  | table | 16 kB | 16 kB  | 16 kB  | Aircraft (translations) |
| <code>airports</code>        | view  |       |        |        | Airports                |
| <code>airports_data</code>   | table | 56 kB | 56 kB  | 56 kB  | Airports (translations) |
| <code>boarding_passes</code> | table | 31 MB | 102 MB | 427 MB | Boarding passes         |
| <code>bookings</code>        | table | 13 MB | 30 MB  | 105 MB | Bookings                |
| <code>flights</code>         | table | 3 MB  | 6 MB   | 19 MB  | Flights                 |
| <code>flights_v</code>       | view  |       |        |        | Flights                 |
| <code>routes</code>          | view  |       |        |        | Routes                  |
| <code>seats</code>           | table | 88 kB | 88 kB  | 88 kB  | Seats                   |
| <code>ticket_flights</code>  | table | 64 MB | 145 MB | 516 MB | Flight segments         |
| <code>tickets</code>         | table | 47 MB | 107 MB | 381 MB | Tickets                 |

### N.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See [Section N.4.15](#) for details.

| Column                     | Type                 | Modifiers             | Description                 |
|----------------------------|----------------------|-----------------------|-----------------------------|
| <code>aircraft_code</code> | <code>char(3)</code> | <code>not null</code> | Aircraft code, IATA         |
| <code>model</code>         | <code>text</code>    | <code>not null</code> | Aircraft model              |
| <code>range</code>         | <code>integer</code> | <code>not null</code> | Maximal flying distance, km |

View definition:

```
SELECT ml.aircraft_code,
       ml.model ->> lang() AS model,
       ml.range
FROM   aircrafts_data ml;
```

### N.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

| Column                     | Type                 | Modifiers             | Description         |
|----------------------------|----------------------|-----------------------|---------------------|
| <code>aircraft_code</code> | <code>char(3)</code> | <code>not null</code> | Aircraft code, IATA |

```

model          | jsonb   | not null   | Aircraft model
range          | integer | not null   | Maximal flying distance, km

```

Indexes:

```
PRIMARY KEY, btree (aircraft_code)
```

Check constraints:

```
CHECK (range > 0)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code)
TABLE "seats" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE

```

#### N.4.4. View `bookings.airports`

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See [Section N.4.15](#) for details.

| Column                    | Type                 | Modifiers             | Description                                  |
|---------------------------|----------------------|-----------------------|----------------------------------------------|
| <code>airport_code</code> | <code>char(3)</code> | <code>not null</code> | Airport code                                 |
| <code>airport_name</code> | <code>text</code>    | <code>not null</code> | Airport name                                 |
| <code>city</code>         | <code>text</code>    | <code>not null</code> | City                                         |
| <code>coordinates</code>  | <code>point</code>   | <code>not null</code> | Airport coordinates (longitude and latitude) |
| <code>timezone</code>     | <code>text</code>    | <code>not null</code> | Airport time zone                            |

View definition:

```

SELECT ml.airport_code,
       ml.airport_name ->> lang() AS airport_name,
       ml.city ->> lang() AS city,
       ml.coordinates,
       ml.timezone
FROM airports_data ml;

```

#### N.4.5. Table `bookings.airports_data`

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

| Column                    | Type                 | Modifiers             | Description                                  |
|---------------------------|----------------------|-----------------------|----------------------------------------------|
| <code>airport_code</code> | <code>char(3)</code> | <code>not null</code> | Airport code                                 |
| <code>airport_name</code> | <code>jsonb</code>   | <code>not null</code> | Airport name                                 |
| <code>city</code>         | <code>jsonb</code>   | <code>not null</code> | City                                         |
| <code>coordinates</code>  | <code>point</code>   | <code>not null</code> | Airport coordinates (longitude and latitude) |
| <code>timezone</code>     | <code>text</code>    | <code>not null</code> | Airport time zone                            |

Indexes:

```
PRIMARY KEY, btree (airport_code)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (arrival_airport)
REFERENCES airports_data(airport_code)
TABLE "flights" FOREIGN KEY (departure_airport)
REFERENCES airports_data(airport_code)

```

### N.4.6. Table `bookings.boarding_passes`

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (`boarding_no`), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (`seat_no`).

| Column                   | Type                    | Modifiers             | Description          |
|--------------------------|-------------------------|-----------------------|----------------------|
| <code>ticket_no</code>   | <code>char(13)</code>   | <code>not null</code> | Ticket number        |
| <code>flight_id</code>   | <code>integer</code>    | <code>not null</code> | Flight ID            |
| <code>boarding_no</code> | <code>integer</code>    | <code>not null</code> | Boarding pass number |
| <code>seat_no</code>     | <code>varchar(4)</code> | <code>not null</code> | Seat number          |

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
UNIQUE CONSTRAINT, btree (flight_id, seat_no)

### N.4.7. Table `bookings.bookings`

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (`book_date`, not earlier than one month before the flight). The booking is identified by its number (`book_ref`, a six-position combination of letters and digits).

The `total_amount` field stores the total cost of all tickets included into the booking, for all passengers.

| Column                    | Type                       | Modifiers             | Description        |
|---------------------------|----------------------------|-----------------------|--------------------|

```

### N.4.8. Table `bookings.flights`

The natural key of the `bookings.flights` table consists of two fields — `flight_no` and `scheduled_departure`. To make foreign keys for this table more compact, a surrogate key is used as the primary key (`flight_id`).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

**Flight status** (*status*) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

| Column              | Type        | Modifiers | Description              |
|---------------------|-------------|-----------|--------------------------|
| flight_id           | serial      | not null  | Flight ID                |

### N.4.9. Table `bookings.seats`

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): Economy, Comfort or Business.

| Column                       | Type                     | Modifiers             | Description         |

### N.4.10. Table `bookings.ticket_flights`

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

| Column                       | Type                       | Modifiers             | Description   |

```

```
REFERENCES ticket_flights(ticket_no, flight_id)
```

### N.4.11. Table `bookings.tickets`

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

| Column                      | Type                     | Modifiers             | Description    |
|-----------------------------|--------------------------|-----------------------|----------------|
| <code>ticket_no</code>      | <code>char(13)</code>    | <code>not null</code> | Ticket number  |
| <code>book_ref</code>       | <code>char(6)</code>     | <code>not null</code> | Booking number |
| <code>passenger_id</code>   | <code>varchar(20)</code> | <code>not null</code> | Passenger ID   |
| <code>passenger_name</code> | <code>text</code>        | <code>not null</code> | Passenger name |

### N.4.12. View `bookings.flights_v`

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

| Column                                 | Type                     | Description                                                       |
|----------------------------------------|--------------------------|-------------------------------------------------------------------|
| <code>flight_id</code>                 | <code>integer</code>     | Flight ID                                                         |
| <code>flight_no</code>                 | <code>char(6)</code>     | Flight number                                                     |
| <code>scheduled_departure</code>       | <code>timestamp</code>   | Scheduled departure time                                          |

| <code>actual_departure</code>          | <code>timestamp</code>   | Actual departure time                                             |
| <code>actual_departure_local</code>    | <code>timestamp</code>   | Actual departure time,<br>local time at the point of departure    |
| <code>actual_arrival</code>            | <code>timestamp</code>   | Actual arrival time                                               |
| <code>actual_arrival_local</code>      | <code>timestamp</code>   | Actual arrival time,<br>local time at the point of destination    |
| <code>actual_duration</code>           | <code>interval</code>    | Actual flight duration                                            |

### N.4.13. View `bookings.routes`

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

| Column | Type | Description |
|--------|------|-------------|
|--------|------|-------------|

|                        |           |                                                 |
|------------------------|-----------|-------------------------------------------------|
| flight_no              | char(6)   | Flight number                                   |
| departure_airport      | char(3)   | Departure airport code                          |
| departure_airport_name | text      | Departure airport name                          |
| departure_city         | text      | City of departure                               |
| arrival_airport        | char(3)   | Arrival airport code                            |
| arrival_airport_name   | text      | Arrival airport name                            |
| arrival_city           | text      | City of arrival                                 |
| aircraft_code          | char(3)   | Aircraft code, IATA                             |
| duration               | interval  | Flight duration                                 |
| days_of_week           | integer[] | Days of the week on which flights are performed |

#### N.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

#### N.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the `bookings.lang` parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

### N.5. Usage

#### N.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

#### N.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the `bookings.lang` parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see [Section 19.1](#).

In the examples below, the English language is selected for translatable fields.

### N.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

| aircraft_code | model               | range |
|---------------|---------------------|-------|
| 773           | Boeing 777-300      | 11100 |
| 763           | Boeing 767-300      | 7900  |
| SU9           | Sukhoi SuperJet-100 | 3000  |
| 320           | Airbus A320-200     | 5700  |
| 321           | Airbus A321-200     | 5600  |
| 319           | Airbus A319-100     | 6700  |
| 733           | Boeing 737-300      | 4200  |
| CN1           | Cessna 208 Caravan  | 1200  |
| CR2           | Bombardier CRJ-200  | 2700  |

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT  a.aircraft_code,
        a.model,
        s.seat_no,
        s.fare_conditions
FROM    aircrafts a
        JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE   a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

| aircraft_code | model              | seat_no | fare_conditions |
|---------------|--------------------|---------|-----------------|
| CN1           | Cessna 208 Caravan | 1A      | Economy         |
| CN1           | Cessna 208 Caravan | 1B      | Economy         |
| CN1           | Cessna 208 Caravan | 2A      | Economy         |
| CN1           | Cessna 208 Caravan | 2B      | Economy         |
| CN1           | Cessna 208 Caravan | 3A      | Economy         |
| CN1           | Cessna 208 Caravan | 3B      | Economy         |
| CN1           | Cessna 208 Caravan | 4A      | Economy         |
| CN1           | Cessna 208 Caravan | 4B      | Economy         |
| CN1           | Cessna 208 Caravan | 5A      | Economy         |
| CN1           | Cessna 208 Caravan | 5B      | Economy         |
| CN1           | Cessna 208 Caravan | 6A      | Economy         |
| CN1           | Cessna 208 Caravan | 6B      | Economy         |

(12 rows)

Bigger aircraft have more seats of various travel classes:

```
SELECT  s2.aircraft_code,
```

```

        string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
                    ', ') as fare_conditions
FROM      (
        SELECT    s.aircraft_code, s.fare_conditions, count(*) as num
        FROM      seats s
        GROUP BY  s.aircraft_code, s.fare_conditions
        ORDER BY  s.aircraft_code, s.fare_conditions
        ) s2
GROUP BY  s2.aircraft_code
ORDER BY  s2.aircraft_code;

```

| aircraft_code | fare_conditions                            |
|---------------|--------------------------------------------|
| 319           | Business (20), Economy (96)                |
| 320           | Business (20), Economy (120)               |
| 321           | Business (28), Economy (142)               |
| 733           | Business (12), Economy (118)               |
| 763           | Business (30), Economy (192)               |
| 773           | Business (30), Comfort (48), Economy (324) |
| CN1           | Economy (12)                               |
| CR2           | Economy (50)                               |
| SU9           | Business (12), Economy (85)                |

(9 rows)

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```

SELECT    a.airport_code as code,
          a.airport_name,
          a.city,
          a.coordinates
FROM      airports a
WHERE     a.city IN (
          SELECT    aa.city
          FROM      airports aa
          GROUP BY  aa.city
          HAVING    COUNT(*) > 1
          )
ORDER BY  a.city, a.airport_code;

```

| code | airport_name           | city      | coordinates                          |
|------|------------------------|-----------|--------------------------------------|
| DME  | Domodedovo             | Moscow    | (37.9062995910645, 55.4087982177734) |
|      | International Airport  |           |                                      |
| SVO  | Sheremetyevo           | Moscow    | (37.4146, 55.972599)                 |

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = 'Volgograd';
```

| city        | code | airport_name                       | days_of_week    | duration |
|-------------|------|------------------------------------|-----------------|----------|
| Moscow      | SVO  | Sheremetyevo International Airport | {1,2,3,4,5,6,7} | 01:15:00 |
| Chelyabinsk | CEK  | Chelyabinsk Balandino Airport      | {1,2,3,4,5,6,7} | 01:50:00 |
| Rostov      | ROV  | Rostov-on-Don Airport              | {1,2,3,4,5,6,7} | 00:30:00 |
| Moscow      | VKO  | Vnukovo International Airport      | {1,2,3,4,5,6,7} | 01:10:00 |
| Cheboksary  | CSY  | Cheboksary Airport                 | {1,2,3,4,5,6,7} | 02:45:00 |
| Tomsk       | TOF  | Bogashevo Airport                  | {1}             | 03:50:00 |

(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

| now                    |
|------------------------|
| 2017-08-15 18:00:00+03 |

In relation to this moment, all flights are classified as past and future flights:

```
SELECT  status,
        count(*) as count,
        min(scheduled_departure) as min_scheduled_departure,
        max(scheduled_departure) as max_scheduled_departure
FROM    flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

| status    | count | min_scheduled_departure | max_scheduled_departure |
|-----------|-------|-------------------------|-------------------------|
| Arrived   | 16707 | 2017-07-16 01:50:00+03  | 2017-08-15 17:25:00+03  |
| Cancelled | 414   | 2017-07-19 11:35:00+03  | 2017-09-14 20:55:00+03  |
| Departed  | 58    | 2017-08-15 09:55:00+03  | 2017-08-15 17:50:00+03  |
| Delayed   | 41    | 2017-08-15 15:15:00+03  | 2017-08-16 17:25:00+03  |
| On Time   | 518   | 2017-08-15 17:55:00+03  | 2017-08-16 18:00:00+03  |
| Scheduled | 15383 | 2017-08-16 18:05:00+03  | 2017-09-14 20:40:00+03  |

(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT f.*
FROM   flights_v f
WHERE  f.departure_city = 'Yekaterinburg'
AND    f.arrival_city = 'Moscow'
```

```
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT    1;
```

```
-[ RECORD 1 ]-----+-----
flight_id      | 10927
flight_no      | PG0226
scheduled_departure | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival | 2017-08-16 09:55:00+03
scheduled_arrival_local | 2017-08-16 09:55:00
scheduled_duration | 01:45:00
departure_airport | SVX
departure_airport_name | Koltsovo Airport
departure_city | Yekaterinburg
arrival_airport | SVO
arrival_airport_name | Sheremetyevo International Airport
arrival_city | Moscow
status | On Time
aircraft_code | 773
actual_departure |
actual_departure_local |
actual_arrival |
actual_arrival_local |
actual_duration |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

## N.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT *
FROM bookings
ORDER BY total_amount desc
LIMIT 10;
```

| book_ref | book_date              | total_amount |
|----------|------------------------|--------------|
| 3B54BB   | 2017-07-05 17:08:00+03 | 1204500.00   |
| 3AC131   | 2017-07-31 01:06:00+03 | 1087100.00   |
| 65A6EA   | 2017-07-03 06:28:00+03 | 1065600.00   |
| D7E9AA   | 2017-08-08 05:29:00+03 | 1062800.00   |
| EF479E   | 2017-08-02 15:58:00+03 | 1035100.00   |
| 521C53   | 2017-07-08 09:25:00+03 | 985500.00    |
| 514CA6   | 2017-07-27 05:07:00+03 | 955000.00    |
| D70BD9   | 2017-07-05 12:47:00+03 | 947500.00    |
| EC7EDA   | 2017-07-02 16:13:00+03 | 946800.00    |
| 8E4370   | 2017-07-28 02:04:00+03 | 945700.00    |

(10 rows)

Let's take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

| ticket_no     | passenger_id | passenger_name     |
|---------------|--------------|--------------------|
| 0005432661914 | 8234 547529  | IVAN IVANOV        |
| 0005432661915 | 2034 201228  | ANTONINA KUZNECOVA |

(2 rows)

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        tf.fare_conditions AS class,
        tf.amount
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

| when       | departure             | arrival               | class    | amount    |
|------------|-----------------------|-----------------------|----------|-----------|
| 29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Business | 185300.00 |
| 02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Business | 92200.00  |
| 03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS) | Business | 18000.00  |
| 08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV)      | Business | 18000.00  |
| 12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYR)          | Economy  | 30700.00  |
| 17.08.2017 | Anadyr (DYR)          | Moscow (SVO)          | Business | 185300.00 |

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        f.status,
        bp.seat_no
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
        LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
        AND tf.ticket_no = bp.ticket_no
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

| when | departure | arrival | status | seat_no |
|------|-----------|---------|--------|---------|
|------|-----------|---------|--------|---------|

```
29.07.2017 | Moscow (SVO)          | Anadyr (DYZ)          | Arrived   | 5C
02.08.2017 | Anadyr (DYZ)          | Khabarovsk (KHV)      | Arrived   | 1D
03.08.2017 | Khabarovsk (KHV)      | Blagoveshchensk (BQS) | Arrived   | 2C
08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV)      | Arrived   | 2D
12.08.2017 | Khabarovsk (KHV)      | Anadyr (DYZ)          | Arrived   | 20B
17.08.2017 | Anadyr (DYZ)          | Moscow (SVO)          | Scheduled |
(6 rows)
```

## N.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;
```

```
INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);
```

```
INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');
```

```
INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_0000000000001', 8525, 'Business', 0),
            ('_0000000000001', 4967, 'Business', 0);
```

```
COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```
INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_0000000000001', 8525, 1, '1A');
```

Now let's check the booking information:

```
SELECT      b.book_ref,
            t.ticket_no,
            t.passenger_id,
            t.passenger_name,
            tf.fare_conditions,
            tf.amount,
            f.scheduled_departure_local,
            f.scheduled_arrival_local,
            f.departure_city || ' (' || f.departure_airport || ')' AS departure,
            f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
            f.status,
            bp.seat_no
FROM        bookings b
            JOIN tickets t ON b.book_ref = t.book_ref
            JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
            JOIN flights_v f ON tf.flight_id = f.flight_id
            LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                AND tf.ticket_no = bp.ticket_no
WHERE       b.book_ref = '_QWE12'
```

ORDER BY t.ticket\_no, f.scheduled\_departure;

```
-[ RECORD 1 ]-----+-----
book_ref      | _QWE12

# Appendix P. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACID                         | <i>Atomicity</i> , <i>Consistency</i> , <i>Isolation</i> , and <i>Durability</i> . This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.                                                                                                                                                                                          |
| Aggregate function (routine) | <p>A <i>function</i> that combines (<i>aggregates</i>) multiple input values, for example by counting, averaging or adding, yielding a single output value.</p> <p>For more information, see <a href="#">Section 9.21</a>.</p> <p>See Also <a href="#">Window function (routine)</a>.</p>                                                                                                                                               |
| Analytic function            | See <a href="#">Window function (routine)</a> .                                                                                                                                                                                                                                                                                                                                                                                         |
| Analyze (operation)          | <p>The act of collecting statistics from data in <i>tables</i> and other <i>relations</i> to help the <i>query planner</i> to make decisions about how to execute <i>queries</i>.</p> <p>(Don't confuse this term with the <code>ANALYZE</code> option to the <code>EXPLAIN</code> command.)</p> <p>For more information, see <a href="#">ANALYZE</a>.</p>                                                                              |
| Atomic                       | <p>In reference to a <i>datum</i>: the fact that its value cannot be broken down into smaller components.</p> <p>In reference to a <i>database transaction</i>: see <i>atomicity</i>.</p>                                                                                                                                                                                                                                               |
| Atomicity                    | The property of a <i>transaction</i> that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.                                                                                                                                                             |
| Attribute                    | An element with a certain name and data type found within a <i>tuple</i> .                                                                                                                                                                                                                                                                                                                                                              |
| Autovacuum (process)         | <p>A set of background processes that routinely perform <i>vacuum</i> and <i>analyze</i> operations. The <i>auxiliary process</i> that coordinates the work and is always present (unless autovacuum is disabled) is known as the <i>autovacuum launcher</i>, and the processes that carry out the tasks are known as the <i>autovacuum workers</i>.</p> <p>For more information, see <a href="#">Section 24.1.6</a>.</p>               |
| Auxiliary process            | A process within an <i>instance</i> that is in charge of some specific background task for the instance. The auxiliary processes consist of the <i>autovacuum launcher</i> (but not the autovacuum workers), the <i>background writer</i> , the <i>checkpointer</i> , the <i>logger</i> , the <i>startup process</i> , the <i>WAL archiver</i> , the <i>WAL receiver</i> (but not the <i>WAL senders</i> ), and the <i>WAL writer</i> . |
| Backend (process)            | <p>Process of an <i>instance</i> which acts on behalf of a <i>client session</i> and handles its requests.</p> <p>(Don't confuse this term with the similar terms <i>Background Worker</i> or <i>Background Writer</i>).</p>                                                                                                                                                                                                            |
| Background worker (process)  | Process within an <i>instance</i> , which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as <i>logi-</i>                                                                                                                                                                                                                                                                         |

*cal replication* and *parallel queries*. In addition, *Extensions* can add custom background worker processes.

For more information, see [Chapter 51](#).

**Background writer (process)** An *auxiliary process* that writes dirty *data pages* from *shared memory* to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes.

For more information, see [Section 19.4.5](#).

**Base Backup** A binary copy of all *database cluster* files. It is generated by the tool *pg\_basebackup*. In combination with WAL files it can be used as the starting point for recovery, log shipping, or streaming replication.

**BiHA cluster** A *database cluster* with built-in high availability configured by means of the *BiHA solution*.

See also *leader*, *follower*, and *referee*.

**Bloat** Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.

**Bootstrap superuser** The first *user* initialized in a *database cluster*.  
  
This user owns all system catalog tables in each database. It is also the role from which all granted permissions originate. Because of these things, this role may not be dropped.

This role also behaves as a normal *database superuser*.

**Buffer Access Strategy** Some operations will access a large number of *pages*. A *Buffer Access Strategy* helps to prevent these operations from evicting too many pages from *shared buffers*.

A Buffer Access Strategy sets up references to a limited number of *shared buffers* and reuses them circularly. When the operation requires a new page, a victim buffer is chosen from the buffers in the strategy ring, which may require flushing the page's dirty data and possibly also unflushed *WAL* to permanent storage.

Buffer Access Strategies are used for various operations such as sequential scans of large tables, *VACUUM*, *COPY*, *CREATE TABLE AS SELECT*, *ALTER TABLE*, *CREATE DATABASE*, *CREATE INDEX*, and *CLUSTER*.

**Cast** A conversion of a *datum* from its current data type to another data type.

For more information, see [CREATE CAST](#).

**Catalog** The SQL standard uses this term to indicate what is called a *database* in PostgreSQL's terminology.

(Don't confuse this term with *system catalog*).

For more information, see [Section 22.1](#).

**Check constraint** A type of *constraint* defined on a *relation* which restricts the values allowed in one or more *attributes*. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations.

For more information, see [Section 5.4](#).

**Checkpoint**

A point in the [WAL](#) sequence at which it is guaranteed that the heap and index data files have been updated with all information from [shared memory](#) modified before that checkpoint; a *checkpoint record* is written and flushed to WAL to mark that point.

A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when pre-defined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command `CHECKPOINT`.

For more information, see [Section 30.5](#).

**Checkpointing (process)**

An [auxiliary process](#) that is responsible for executing *checkpoints*.

**Class (archaic)**

See [Relation](#).

**Client (process)**

Any process, possibly remote, that establishes a [session](#) by [connecting](#) to an [instance](#) to interact with a [database](#).

**Cluster owner**

The operating system user that owns the [data directory](#) and under which the `postgres` process is run. It is required that this user exist prior to creating a new [database cluster](#).

On operating systems with a `root` user, said user is not allowed to be the cluster owner.

**Column**

An [attribute](#) found in a [table](#) or [view](#).

**Commit**

The act of finalizing a [transaction](#) within the [database](#), which makes it visible to other transactions and assures its [durability](#).

For more information, see [COMMIT](#).

**Concurrency**

The concept that multiple independent operations happen within the [database](#) at the same time. In PostgreSQL, concurrency is controlled by the [multiversion concurrency control](#) mechanism.

**Connection**

An established line of communication between a client process and a [back-end](#) process, usually over a network, supporting a [session](#). This term is sometimes used as a synonym for session.

For more information, see [Section 19.3](#).

**Consistency**

The property that the data in the [database](#) is always in compliance with [integrity constraints](#). Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved by the time it commits, such a transaction is automatically [rolled back](#). This is one of the ACID properties.

**Constraint**

A restriction on the values of data allowed within a [table](#), or in attributes of a [domain](#).

For more information, see [Section 5.4](#).

**Cumulative  
System Statistics**

A system which, if enabled, accumulates statistical information about the [instance](#)'s activities.

For more information, see [Section 28.2](#).

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data area          | See <a href="#">Data directory</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Database           | <p>A named collection of <a href="#">local SQL objects</a>.</p> <p>For more information, see <a href="#">Section 22.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Database cluster   | <p>A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>. A database cluster is created using the <a href="#">initdb</a> program.</p> <p>In PostgreSQL, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.)</p> <p>See also <a href="#">cluster owner</a>, the operating-system owner of a cluster, and <a href="#">bootstrap superuser</a>, the PostgreSQL owner of a cluster.</p> |
| Database server    | See <a href="#">Instance</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Database superuser | <p>A role having <i>superuser status</i> (see <a href="#">Section 21.2</a>).</p> <p>Frequently referred to as <i>superuser</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Data directory     | <p>The base directory on the file system of a <a href="#">server</a> that contains all data files and subdirectories associated with a <a href="#">database cluster</a> (with the exception of <a href="#">tablespaces</a>, and optionally <a href="#">WAL</a>). The environment variable <code>PGDATA</code> is commonly used to refer to the data directory.</p> <p>A <a href="#">cluster</a>'s storage space comprises the data directory plus any additional tablespaces.</p> <p>For more information, see <a href="#">Section 74.1</a>.</p>                 |
| Data page          | The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to <a href="#">shared buffers</a> where they can be modified, becoming <i>dirty</i> . They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.                                                                                                                                                                                  |
| Datum              | The internal representation of one value of an SQL data type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Delete             | <p>An SQL command which removes <a href="#">rows</a> from a given <a href="#">table</a> or <a href="#">relation</a>.</p> <p>For more information, see <a href="#">DELETE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                |
| Domain             | <p>A user-defined data type that is based on another underlying data type. It acts the same as the underlying type except for possibly restricting the set of allowed values.</p> <p>For more information, see <a href="#">Section 8.18</a>.</p>                                                                                                                                                                                                                                                                                                                 |
| Durability         | The assurance that once a <a href="#">transaction</a> has been <a href="#">committed</a> , the changes remain even after a system failure or crash. This is one of the ACID properties.                                                                                                                                                                                                                                                                                                                                                                          |
| Extension          | <p>A software add-on package that can be installed on an <a href="#">instance</a> to get extra features.</p> <p>For more information, see <a href="#">Section 41.17</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                     |
| File segment       | A physical file which stores data for a given <a href="#">relation</a> . File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments.                                                                                                                                                                                                                                                                                                                              |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <p>For more information, see <a href="#">Section 74.1</a>.</p> <p>(Don't confuse this term with the similar term <a href="#">WAL segment</a>).</p>                                                                                                                                                                                                                                                                                                                                  |
| Follower (node)          | <p>A <a href="#">replica</a> of the <a href="#">leader</a> in the <a href="#">BiHA cluster</a>.</p> <p>See also <a href="#">referee</a>.</p>                                                                                                                                                                                                                                                                                                                                        |
| Foreign data wrapper     | <p>A means of representing data that is not contained in the local <a href="#">database</a> so that it appears as if were in local <a href="#">table(s)</a>. With a foreign data wrapper it is possible to define a <a href="#">foreign server</a> and <a href="#">foreign tables</a>.</p> <p>For more information, see <a href="#">CREATE FOREIGN DATA WRAPPER</a>.</p>                                                                                                            |
| Foreign key              | <p>A type of <a href="#">constraint</a> defined on one or more <a href="#">columns</a> in a <a href="#">table</a> which requires the value(s) in those <a href="#">columns</a> to identify zero or one <a href="#">row</a> in another (or, infrequently, the same) <a href="#">table</a>.</p>                                                                                                                                                                                       |
| Foreign server           | <p>A named collection of <a href="#">foreign tables</a> which all use the same <a href="#">foreign data wrapper</a> and have other configuration values in common.</p> <p>For more information, see <a href="#">CREATE SERVER</a>.</p>                                                                                                                                                                                                                                              |
| Foreign table (relation) | <p>A <a href="#">relation</a> which appears to have <a href="#">rows</a> and <a href="#">columns</a> similar to a regular <a href="#">table</a>, but will forward requests for data through its <a href="#">foreign data wrapper</a>, which will return <a href="#">result sets</a> structured according to the definition of the <a href="#">foreign table</a>.</p> <p>For more information, see <a href="#">CREATE FOREIGN TABLE</a>.</p>                                         |
| Fork                     | <p>Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the <a href="#">free space map</a> and the <a href="#">visibility map</a>. <a href="#">Unlogged relations</a> also have an <i>init fork</i>.</p>                                                                                                                                               |
| Free space map (fork)    | <p>A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size.</p> <p>For more information, see <a href="#">Section 74.3</a>.</p>                                                                                                             |
| Function (routine)       | <p>A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via <code>SELECT</code>. Certain functions can return <a href="#">sets</a>; those are called <i>set-returning functions</i>.</p> <p>Functions can also be used for <a href="#">triggers</a> to invoke.</p> <p>For more information, see <a href="#">CREATE FUNCTION</a>.</p> |
| GMT                      | <p>See <a href="#">UTC</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Grant                    | <p>An SQL command that is used to allow a <a href="#">user</a> or <a href="#">role</a> to access specific objects within the <a href="#">database</a>.</p> <p>For more information, see <a href="#">GRANT</a>.</p>                                                                                                                                                                                                                                                                  |
| Heap                     | <p>Contains the values of <a href="#">row</a> attributes (i.e., the data) for a <a href="#">relation</a>. The heap is realized within one or more <a href="#">file segments</a> in the relation's <i>main fork</i>.</p>                                                                                                                                                                                                                                                             |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host                      | <p>A computer that communicates with other computers over a network. This is sometimes used as a synonym for <a href="#">server</a>. It is also used to refer to a computer where <a href="#">client processes</a> run.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Index (relation)          | <p>A <a href="#">relation</a> that contains data derived from a <a href="#">table</a> or <a href="#">materialized view</a>. Its internal structure supports fast retrieval of and access to the original data.</p> <p>For more information, see <a href="#">CREATE INDEX</a>.</p>                                                                                                                                                                                                                                                                                                                                                                         |
| Insert                    | <p>An SQL command used to add new data into a <a href="#">table</a>.</p> <p>For more information, see <a href="#">INSERT</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Instance                  | <p>A group of <a href="#">backend</a> and <a href="#">auxiliary processes</a> that communicate using a common shared memory area. One <a href="#">postmaster process</a> manages the instance; one instance manages exactly one <a href="#">database cluster</a> with all its databases. Many instances can run on the same <a href="#">server</a> as long as their TCP ports do not conflict.</p> <p>The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, <a href="#">connections to client processes</a>, privilege verification, crash recovery, replication, etc.</p> |
| Isolation                 | <p>The property that the effects of a transaction are not visible to <a href="#">concurrent transactions</a> before it commits. This is one of the ACID properties.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Join                      | <p>An operation and SQL keyword used in <a href="#">queries</a> for combining data from multiple <a href="#">relations</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Key                       | <p>A means of identifying a <a href="#">row</a> within a <a href="#">table</a> or other <a href="#">relation</a> by values contained within one or more <a href="#">attributes</a> in that relation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Leader (node)             | <p>A <a href="#">primary server</a> in the <a href="#">BiHA cluster</a>.</p> <p>See also <a href="#">follower</a> and <a href="#">referee</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Lock                      | <p>A mechanism that allows a process to limit or prevent simultaneous access to a resource.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Log file                  | <p>Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc.</p> <p>For more information, see <a href="#">Section 24.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Logged                    | <p>A <a href="#">table</a> is considered <a href="#">logged</a> if changes to it are sent to the <a href="#">WAL</a>. By default, all regular tables are logged. A table can be specified as <a href="#">unlogged</a> either at creation time or via the <code>ALTER TABLE</code> command.</p>                                                                                                                                                                                                                                                                                                                                                            |
| Logger (process)          | <p>An <a href="#">auxiliary process</a> which, if enabled, writes information about database events into the current <a href="#">log file</a>. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called <a href="#">syslogger</a>.</p> <p>For more information, see <a href="#">Section 19.8</a>.</p>                                                                                                                                                                                                                                                                                                             |
| Log record                | <p>Archaic term for a <a href="#">WAL record</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Log sequence number (LSN) | <p>Byte offset into the <a href="#">WAL</a>, increasing monotonically with each new <a href="#">WAL record</a>.</p> <p>For more information, see <a href="#">pg_lsn</a> and <a href="#">Section 30.7</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| LSN                                      | See <a href="#">Log sequence number</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Master (server)                          | See <a href="#">Primary (server)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Materialized                             | <p>The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly.</p> <p>This term is used in <a href="#">materialized view</a>, to mean that the data derived from the view's query is stored on disk separately from the sources of that data.</p> <p>This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.</p>                                                                                                                                        |
| Materialized view (relation)             | <p>A <a href="#">relation</a> that is defined by a <code>SELECT</code> statement (just like a <a href="#">view</a>), but stores data in the same way that a <a href="#">table</a> does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, or <code>MERGE</code> operations.</p> <p>For more information, see <a href="#">CREATE MATERIALIZED VIEW</a>.</p>                                                                                                                                                                                                                                                                                                         |
| Merge                                    | <p>An SQL command used to conditionally add, modify, or remove <a href="#">rows</a> in a given <a href="#">table</a>, using data from a source <a href="#">relation</a>.</p> <p>For more information, see <a href="#">MERGE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Multi-version concurrency control (MVCC) | A mechanism designed to allow several <a href="#">transactions</a> to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies ( <i>versions</i> ) of <a href="#">tuples</a> as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.                                                                                                                                                                                                                                                                                                             |
| Null                                     | A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Optimizer                                | See <a href="#">Query planner</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Parallel query                           | The ability to handle parts of executing a <a href="#">query</a> to take advantage of parallel processes on servers with multiple CPUs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Partition                                | <p>One of several disjoint (not overlapping) subsets of a larger set.</p> <p>In reference to a <a href="#">partitioned table</a>: One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i>. The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created.</p> <p>In reference to a <a href="#">window function</a> in a <a href="#">query</a>, a partition is a user-defined criterion that identifies which neighboring <a href="#">rows</a> of the <a href="#">query's result set</a> can be considered by the function.</p> |
| Partitioned table (relation)             | A <a href="#">relation</a> that is in semantic terms the same as a <a href="#">table</a> , but whose storage is distributed across several <a href="#">partitions</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Postmaster (process)                     | <p>The very first process of an <a href="#">instance</a>. It starts and manages the <a href="#">auxiliary processes</a> and creates <a href="#">backend processes</a> on demand.</p> <p>For more information, see <a href="#">Section 18.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Primary key                              | A special case of a <a href="#">unique constraint</a> defined on a <a href="#">table</a> or other <a href="#">relation</a> that also guarantees that all of the <a href="#">attributes</a> within the <a href="#">primary key</a> do not                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                       | have <a href="#">null</a> values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.                                                                                                                                                                                                                                                                                                                                                                |
| Primary (server)      | When two or more <a href="#">databases</a> are linked via <a href="#">replication</a> , the <a href="#">server</a> that is considered the authoritative source of information is called the <i>primary</i> , also known as a <i>master</i> .                                                                                                                                                                                                                                                                                                                            |
| Procedure (routine)   | <p>A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as <code>COMMIT</code> and <code>ROLLBACK</code>. They are invoked via the <code>CALL</code> command.</p> <p>For more information, see <a href="#">CREATE PROCEDURE</a>.</p>                                                                                                                                                                                                                                      |
| Query                 | A request sent by a client to a <a href="#">backend</a> , usually to return results or to modify data on the database.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Query planner         | The part of PostgreSQL that is devoted to determining ( <i>planning</i> ) the most efficient way to execute <a href="#">queries</a> . Also known as <i>query optimizer</i> , <i>optimizer</i> , or simply <i>planner</i> .                                                                                                                                                                                                                                                                                                                                              |
| Record                | See <a href="#">Tuple</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Recycling             | See <a href="#">WAL file</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Referee (node)        | A node that only participates in voting and does not contain any user data. The referee concept is used in the <a href="#">Built-in High Availability (BiHA)</a> solution and the <a href="#">multimaster</a> extension.                                                                                                                                                                                                                                                                                                                                                |
| Referential integrity | A means of restricting data in one <a href="#">relation</a> by a <a href="#">foreign key</a> so that it must have matching data in another <a href="#">relation</a> .                                                                                                                                                                                                                                                                                                                                                                                                   |
| Relation              | <p>The generic term for all objects in a <a href="#">database</a> that have a name and a list of <a href="#">attributes</a> defined in a specific order. <a href="#">Tables</a>, <a href="#">sequences</a>, <a href="#">views</a>, <a href="#">foreign tables</a>, <a href="#">materialized views</a>, composite types, and <a href="#">indexes</a> are all relations.</p> <p>More generically, a relation is a set of tuples; for example, the result of a query is also a relation.</p> <p>In PostgreSQL, <i>Class</i> is an archaic synonym for <i>relation</i>.</p> |
| Replica (server)      | A <a href="#">database</a> that is paired with a <a href="#">primary</a> database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the <a href="#">primary</a> becomes unavailable.                                                                                                                                                                                                                |
| Replication           | The act of reproducing data on one <a href="#">server</a> onto another server called a <a href="#">replica</a> . This can take the form of <i>physical replication</i> , where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.                                                                                                                                                                                                             |
| Restartpoint          | <p>A variant of a <a href="#">checkpoint</a> performed on a <a href="#">replica</a>.</p> <p>For more information, see <a href="#">Section 30.5</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Result set            | <p>A <a href="#">relation</a> transmitted from a <a href="#">backend process</a> to a <a href="#">client</a> upon the completion of an SQL command, usually a <code>SELECT</code> but it can be an <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> command if the <code>RETURNING</code> clause is specified.</p> <p>The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.</p>                                                                                       |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Revoke              | <p>A command to prevent access to a named set of <i>database</i> objects for a named list of <i>roles</i>.</p> <p>For more information, see <a href="#">REVOKE</a>.</p>                                                                                                                                                                                                                                                                                                                                   |
| Role                | <p>A collection of access privileges to the <i>instance</i>. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple <i>users</i> need the same privileges.</p> <p>For more information, see <a href="#">CREATE ROLE</a>.</p>                                                                                                                                                                                     |
| Rollback            | <p>A command to undo all of the operations performed since the beginning of a <i>transaction</i>.</p> <p>For more information, see <a href="#">ROLLBACK</a>.</p>                                                                                                                                                                                                                                                                                                                                          |
| Routine             | <p>A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be <i>functions</i> (including set-returning functions and <i>trigger functions</i>), <i>aggregate functions</i>, and <i>procedures</i>.</p> <p>Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.</p>                                                                   |
| Row                 | <p>See <a href="#">Tuple</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Savepoint           | <p>A special mark in the sequence of steps in a <i>transaction</i>. Data modifications after this point in time may be reverted to the time of the savepoint.</p> <p>For more information, see <a href="#">SAVEPOINT</a>.</p>                                                                                                                                                                                                                                                                             |
| Schema              | <p>A schema is a namespace for <i>SQL objects</i>, which all reside in the same <i>database</i>. Each SQL object must reside in exactly one schema.</p> <p>All system-defined SQL objects reside in schema <code>pg_catalog</code>.</p> <p>More generically, the term <i>schema</i> is used to mean all data descriptions (<i>table</i> definitions, <i>constraints</i>, comments, etc.) for a given <i>database</i> or subset thereof.</p> <p>For more information, see <a href="#">Section 5.9</a>.</p> |
| Segment             | <p>See <a href="#">File segment</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Select              | <p>The SQL command used to request data from a <i>database</i>. Normally, <code>SELECT</code> commands are not expected to modify the <i>database</i> in any way, but it is possible that <i>functions</i> invoked within the query could have side effects that do modify data.</p> <p>For more information, see <a href="#">SELECT</a>.</p>                                                                                                                                                             |
| Sequence (relation) | <p>A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate <i>primary key</i> values.</p>                                                                                                                                                                                                                                                                                                   |
| Server              | <p>A computer on which PostgreSQL <i>instances</i> run. The term <i>server</i> denotes real hardware, a container, or a <i>virtual machine</i>.</p> <p>This term is sometimes used to refer to an instance or to a host.</p>                                                                                                                                                                                                                                                                              |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Session          | A state that allows a client and a backend to interact, communicating over a <a href="#">connection</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Shared memory    | <p>RAM which is used by the processes common to an <a href="#">instance</a>. It mirrors parts of <a href="#">database</a> files, provides a transient area for <a href="#">WAL records</a>, and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.</p> <p>The largest part of shared memory is known as <i>shared buffers</i> and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.</p> <p>For more information, see <a href="#">Section 19.4.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SQL object       | <p>Any object that can be created with a <code>CREATE</code> command. Most objects are specific to one database, and are commonly known as <i>local objects</i>.</p> <p>Most local objects reside in a specific <a href="#">schema</a> in their containing database, such as <a href="#">relations</a> (all types), <a href="#">routines</a> (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.</p> <p>There also exist local objects that do not reside in schemas; some examples are <a href="#">extensions</a>, <a href="#">data type casts</a>, and <a href="#">foreign data wrappers</a>. The names of such objects of the same type are enforced to be unique within the database.</p> <p>Other object types, such as <a href="#">roles</a>, <a href="#">tablespaces</a>, replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster.</p> <p>For more information, see <a href="#">Section 22.1</a>.</p> |
| SQL standard     | A series of documents that define the SQL language.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Standby (server) | See <a href="#">Replica (server)</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Startup process  | <p>An <a href="#">auxiliary process</a> that replays WAL during crash recovery and in a <a href="#">physical replica</a>.</p> <p>(The name is historical: the startup process was named before replication was implemented; the name refers to its task as it relates to the server startup following a crash.)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Superuser        | As used in this documentation, it is a synonym for <a href="#">database superuser</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| System catalog   | <p>A collection of <a href="#">tables</a> which describe the structure of all <a href="#">SQL objects</a> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <a href="#">views</a>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see <a href="#">Chapter 40</a>) that expose some of the same and additional information as mandated by the <a href="#">SQL standard</a>.</p> <p>For more information, see <a href="#">Section 5.9</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Table            | <p>A collection of <a href="#">tuples</a> having a common data structure (the same number of <a href="#">attributes</a>, in the same order, having the same name and type per position). A table is the most common form of <a href="#">relation</a> in PostgreSQL.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                               | For more information, see <a href="#">CREATE TABLE</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Tablespace                    | <p>A named location on the server file system. All <a href="#">SQL objects</a> which require storage beyond their definition in the <a href="#">system catalog</a> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called <code>pg_default</code>.</p> <p>For more information, see <a href="#">Section 22.6</a>.</p>                                                                             |
| Temporary table               | <p><a href="#">Tables</a> that exist either for the lifetime of a <a href="#">session</a> or a <a href="#">transaction</a>, as specified at the time of creation. The data in them is not visible to other sessions, and is not <a href="#">logged</a>. Temporary tables are often used to store intermediate data for a multi-step operation.</p> <p>For more information, see <a href="#">CREATE TABLE</a>.</p>                                                                                         |
| TOAST                         | <p>A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table.</p> <p>For more information, see <a href="#">Section 74.2</a>.</p>                                                                                                                                                                                                                                          |
| Transaction                   | <p>A combination of commands that must act as a single <a href="#">atomic</a> command: they all succeed or all fail as a single unit, and their effects are not visible to other <a href="#">sessions</a> until the transaction is complete, and possibly even later, depending on the isolation level.</p> <p>For more information, see <a href="#">Section 13.2</a>.</p>                                                                                                                                |
| Transaction ID                | <p>The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i>.</p> <p>For more information, see <a href="#">Section 8.19</a>.</p>                                                                                                                                                                                                                                                          |
| Transactions per second (TPS) | <p>Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.</p>                                                                                                                                                                                                                                                                                                   |
| Trigger                       | <p>A <a href="#">function</a> which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a <a href="#">relation</a>. A trigger executes within the same <a href="#">transaction</a> as the statement which invoked it, and if the function fails, then the invoking statement also fails.</p> <p>For more information, see <a href="#">CREATE TRIGGER</a>.</p>                                                                                         |
| Tuple                         | <p>A collection of <a href="#">attributes</a> in a fixed order. That order may be defined by the <a href="#">table</a> (or other <a href="#">relation</a>) where the tuple is contained, in which case the tuple is often called a <i>row</i>. It may also be defined by the structure of a result set, in which case it is sometimes called a <i>record</i>.</p>                                                                                                                                         |
| Unique constraint             | <p>A type of <a href="#">constraint</a> defined on a <a href="#">relation</a> which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.</p> <p>Because <a href="#">null values</a> are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.</p> |
| Unlogged                      | <p>The property of certain <a href="#">relations</a> that the changes to them are not reflected in the <a href="#">WAL</a>. This disables replication and crash recovery for these relations.</p>                                                                                                                                                                                                                                                                                                         |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | <p>The primary use of unlogged tables is for storing transient work data that must be shared across processes.</p> <p><i>Temporary tables</i> are always unlogged.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Update                 | <p>An SQL command used to modify <i>rows</i> that may already exist in a specified <i>table</i>. It cannot create or remove rows.</p> <p>For more information, see <a href="#">UPDATE</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| User                   | <p>A <i>role</i> that has the <i>login privilege</i> (see <a href="#">Section 21.2</a>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| User mapping           | <p>The translation of login credentials in the local <i>database</i> to credentials in a remote data system defined by a <i>foreign data wrapper</i>.</p> <p>For more information, see <a href="#">CREATE USER MAPPING</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| UTC                    | <p>Universal Coordinated Time, the primary global time reference, approximately the time prevailing at the zero meridian of longitude. Often but inaccurately referred to as GMT (Greenwich Mean Time).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Vacuum                 | <p>The process of removing outdated <i>tuple versions</i> from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of <i>MVCC</i>. This can be initiated through the use of the <code>VACUUM</code> command, but can also be handled automatically via <i>autovacuum</i> processes.</p> <p>For more information, see <a href="#">Section 24.1</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| View                   | <p>A <i>relation</i> that is defined by a <code>SELECT</code> statement, but has no storage of its own. Any time a query references a view, the definition of the view is substituted into the query as if the user had typed it as a subquery instead of the name of the view.</p> <p>For more information, see <a href="#">CREATE VIEW</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Visibility map (fork)  | <p>A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (<i>all-visible</i>) indicates that all tuples in the page are visible to all transactions. The second one (<i>all-frozen</i>) indicates that all tuples in the page are marked frozen.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| WAL                    | <p>See <a href="#">Write-ahead log</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| WAL archiver (process) | <p>An <i>auxiliary process</i> which, if enabled, saves copies of <i>WAL files</i> for the purpose of creating backups or keeping <i>replicas</i> current.</p> <p>For more information, see <a href="#">Section 25.3</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| WAL file               | <p>Also known as <i>WAL segment</i> or <i>WAL segment file</i>. Each of the sequentially-numbered files that provide storage space for <i>WAL</i>. The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash.</p> <p>Each WAL file can be released after a <i>checkpoint</i> writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called <i>recycling</i>.</p> <p>For more information, see <a href="#">Section 30.7</a>.</p> |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WAL record                | <p>A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (<i>replayed</i>) in case a system failure causes the change to be lost. WAL records use a non-printable binary format.</p> <p>For more information, see <a href="#">Section 30.7</a>.</p>                                                                                                                                                                                                                                           |
| WAL receiver (process)    | <p>An <a href="#">auxiliary process</a> that runs on a <a href="#">replica</a> to receive WAL from the <a href="#">primary server</a> for replay by the <a href="#">startup process</a>.</p> <p>For more information, see <a href="#">Section 26.2</a>.</p>                                                                                                                                                                                                                                                                                                            |
| WAL segment               | <p>See <a href="#">WAL file</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| WAL sender (process)      | <p>A special <a href="#">backend process</a> that streams WAL over a network. The receiving end can be a <a href="#">WAL receiver</a> in a <a href="#">replica</a>, <a href="#">pg_receivewal</a>, or any other client program that speaks the replication protocol.</p>                                                                                                                                                                                                                                                                                               |
| WAL writer (process)      | <p>An <a href="#">auxiliary process</a> that writes <a href="#">WAL records</a> from <a href="#">shared memory</a> to <a href="#">WAL files</a>.</p> <p>For more information, see <a href="#">Section 19.5</a>.</p>                                                                                                                                                                                                                                                                                                                                                    |
| Window function (routine) | <p>A type of <a href="#">function</a> used in a <a href="#">query</a> that applies to a <a href="#">partition</a> of the query's <a href="#">result set</a>; the function's result is based on values found in <a href="#">rows</a> of the same partition or frame.</p> <p>All <a href="#">aggregate functions</a> can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as <i>analytic functions</i>.</p> <p>For more information, see <a href="#">Section 3.5</a>.</p> |
| Write-ahead log           | <p>The journal that keeps track of the changes in the <a href="#">database cluster</a> as user- and system-invoked operations take place. It comprises many individual <a href="#">WAL records</a> written sequentially to <a href="#">WAL files</a>.</p>                                                                                                                                                                                                                                                                                                              |

# Appendix Q. Color Support

Most programs in the Postgres Pro package can produce colorized console output. This appendix describes how that is configured.

## Q.1. When Color is Used

To use colorized output, set the environment variable `PG_COLORS` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

## Q.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of *key=value* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`note`

used to highlight the text “detail” and “hint” in such messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:note=01;36:locus=01` (`01;31` = bold red, `01;35` = bold magenta, `01;36` = bold cyan, `01` = bold default color).

### Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

---

# Appendix R. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

## R.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See [the release notes for PostgreSQL 12](#) for details on this change.

On Postgres Pro 12 and above, [archive recovery](#), [streaming replication](#), and [PITR](#) are configured using [normal server configuration parameters](#). These are set in `postgresql.conf` or via `ALTER SYSTEM` like any other parameter.

The server will not start if a `recovery.conf` exists.

Postgres Pro 15 and below had a setting `promote_trigger_file`, or `trigger_file` before 12. Use `pg_ctl promote` or call `pg_promote()` to promote a standby instead.

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See [Standby Server Operation](#) for details.

## R.2. Default Roles Renamed to Predefined Roles

PostgreSQL 13 and below used the term “Default Roles”. However, as these roles are not able to actually be changed and are installed as part of the system at initialization time, the more appropriate term to use is “Predefined Roles”. See [Section 21.5](#) for current documentation regarding Predefined Roles, and [the release notes for PostgreSQL 14](#) for details on this change.

## R.3. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see [pg\\_waldump](#) for documentation of `pg_waldump` and see [the release notes for PostgreSQL 10](#) for details on this change.

## R.4. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see [pg\\_resetwal](#) for documentation of `pg_resetwal` and see [the release notes for PostgreSQL 10](#) for details on this change.

## R.5. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see [pg\\_receivewal](#) for documentation of `pg_receivewal` and see [the release notes for PostgreSQL 10](#) for details on this change.
